Abstract  In this paper, a performance of a decorrelating detector for a multirate MC(multi-carrier) DS/CDMA system is analyzed and simulated in a frequency selective Rayleigh fading channel. The performance is compared with that of single rate MC-DS/CDMA system in term of bit error probability. Variable Spreading Length (VSL) is employed for MC-DS/CDMA system as multirate transmission scheme. From simulation result, it is shown that Decorrelator for multirate MC-DS/CDMA achieves high BER performance as well as that of single rate case.

Key Words: Decorrelator, Multicode(MC) access, Multicarrier DS/CDMA, Variable spreading length(VSL), OFDM
multimedia service, multirate system is essential requirement. There are two widely used multirate system strategies such as multicode access (MC) and variable spreading length (VSL) access. In this paper a VSL scheme is employed by several spreading codes to distinguish each user with constant chip rate.

In this paper, decorrelating detector for multirate multichannel DS/CDMA system with VSL algorithm is analyzed and simulated in frequency selective Rayleigh fading channel. By using VSL algorithm to multichannel DS/CDMA decorrelating detector, we can support multirate transmission to multichannel DS/CDMA system. And also maintain the complexity of the conventional multichannel DS/CDMA decorrelator. This paper is organized as follows. In section II, system model and channel model are analyzed. In section III, performance analysis is described. In section IV, numerical and simulation results are presented. Finally, we conclude in section V.

II. System Model

In this section, the proposed transmitter, receiver and channel model are described. And in this paper, $K$ users are considered and Synchronous multichannel DS/CDMA system and BPSK data modulated transmission are assumed.

1. Transmitter Model

The fig. 1 shows a block diagram of a proposed transmitter. The two rate, high and low, BPSK-modulated signals of $k^{th}$ low rate user, $b_{Lk}$, and $j^{th}$ high rate user, $b_{Hj}$, are spread by different length of spreading code, $c_{Lk}(t)$, $c_{Hj}(t)$, each other.

![Block diagram of the proposed multirate multiuser multichannel DS/CDMA detector transmitter.](image)

The chip rate of the low rate data is denoted $N_L$ and the chip rate of the high rate data is denoted $N_H$. It is assumed that the high rate is 2 times of the low rate. And $N_L = 2N_H$ is assumed. So each user has a same rate, different signature waveform. After spreading, each spread signal is serial to parallel converted. And the signals are modulated by $M$ multicarrier. And then are transmitted. The transmitted signal is given by

$$s(t) = \sum_{k=1}^{K} \sqrt{2w_k} c_{Lk}(t) b_{Lk} \sum_{i=1}^{M} \cos(2\pi f_i t + \psi_{ki}) + \sum_{j=1}^{K-N} \sqrt{2w_j} c_{Hj}(t) b_{Hj} \sum_{i=1}^{M} \cos(2\pi f_i t + \psi_{ji})$$

(1)

where $K$ is total number of users, $K$ is total number of the low rate users, $w_k$ and $w_j$ are transmit power of $k^{th}$ low rate user, $j^{th}$ high rate user. So low rate carrier frequency is modulated by a spreading sequence with chip rate $N_L = 2N_H$. And the low high rate carrier frequency is modulated by a spreading
sequency with the chip duration which is $M$ times as long as that of a single carrier system.

2. Channel Model

In this paper, a slow frequency selective Rayleigh fading channel model is used. We denote that its delay spread, the chip duration of proposed detector and the chip duration of the conventional single carrier decorrelating detector are $T_m$, $T_c$ and $T_c'$ ($T_c = m \cdot T_c'$).

For the conventional single carrier decorrelating detector, the frequency selective fading channel for the $k^{th}$ user can be represented as a tapped delay line. The number of resolvable paths in hat model is given by

$$L = \lfloor \frac{T_m}{T_c'} \rfloor + 1,$$

where $\lfloor x \rfloor$ is the integer part of $x$. The complex lowpass equivalent impulse response of the channel of the $k^{th}$ user is given by

$$h_k(t) = \sum_{l=0}^{L-1} \beta_{k,l} e^{j\mu_{k,l}} \delta(t - lT_c'),$$

where $\beta_{k,l}$ and $\mu_{k,l}$ are modeled as zero-mean complex valued stationary Gaussian random variable and uniform random variable over $[0, 2\pi)$.

For proposed detector, the coherence bandwidth of the channel model is given by

$$(\Delta f)_c \approx \frac{1}{T_m}.$$  \hspace{1cm} (4)

Providing that the number of subband multicarrier, $M$, meets the following condition,

$$\frac{T_m}{T_c} = \frac{T_m}{M \cdot T_c'} \leq 1,$$

Each subband of the proposed detector has no selectivity, and besides, if bandwidth of each subband is larger than the coherence bandwidth, all sub-bands are subject to independent fading\textsuperscript{[1]}.

Then, the complex lowpass equivalent impulse response of the $i^{th}$ subcarrier channel of $k^{th}$ user is given by

$$h_{k,i} = \alpha_{k,i} e^{j\phi_{k,i}} \delta(t), \quad i = 1, 2, \ldots, M.$$  \hspace{1cm} (6)

Fig. 2. Block diagram of the proposed multiuser detector receiver.

where $\alpha_{k,i}$ and $\phi_{k,i}$ are i.i.d Rayleigh random variable with a unit second moment and i.i.d uniform random variable over $[0, 2\pi)$.

3. Receiver Model

The received signal is given by

$$r(t) = \sum_{k=1}^{K} \sqrt{2w_k} \alpha_{k,i}c_{k,i}(t)b_{k,i} \sum_{i=1}^{M} \cos(2\pi f_i t + \theta_{k,i}) + \sum_{j=1}^{K} \sqrt{2w_j} \alpha_{j,i} c_{j,i}(t)b_{j,i} \sum_{i=1}^{M} \cos(2\pi f_i t + \theta_{j,i})$$

Where $\theta_{k,i} = \psi_{k,i} + \phi_{k,i}$, $\theta_{j,i} = \psi_{j,i} + \phi_{j,i}$, $n(t)$ is AWGN with a variance $\sigma^2$ and double-sided power spectral density of $\frac{N_0}{2}$, and $n(t)$ is partial narrow-band interference with a p.s.d (power spectral
density) of $S_n(f)$.

Fig. 2 shows a block diagram of the proposed receiver. The received signal is parallel to serial converted and then coherently demodulated for each carrier and passes through the matched filter bank. Its outputs are decorrelated by decorrelating filter. And each decorrelated signals are processed at the energy compensation device.

III. Performance Simulation

To analyze a performance of the proposed detector in term of BER (Bit error rate), followings are assumed.

1) perfect carrier, code and bit synchronization.

2) $G = \frac{T_L}{T_H}$ is integer where $T_L$ is the bit interval of the low rate user and $T_H$ is the bit interval of high rate user.

According to VLS access, in the interval $[0, T_L]$, each high rate user is equivalent to “virtual low rate users” at the receiver. The other words, when the received signals which have difference spreading code length (low and high) are despread each other at the receiver, the high rate user who has $M$ times bit rate of the low rate user’s one can be considered as $M$ virtual low rate users. Therefore, the spreading sequences for the $m$th virtual user of high rate user can be represented by

$$I_{k-H}(t) = \begin{cases} I_{k-H}^{(m)}(t) & \text{for } (m-1)T_H \leq t \leq mT_H, \\ \text{elsewhere} & \end{cases}$$ (8)

The total number of the user can be represented as

$$K_T = K_L + GK_H$$ (9)

where $K_L$ is a number of the low rate users and $K_H$ is a number of the high rate users. The matched filter output put for $i^{th}$ subband carrier branch is given by following matrix form,

$$y_i = \Gamma W Ch + n_i, \quad (10)$$

where

$$b = [b_{1,1}, b_{2,1}, b_{1,2}^{(1)}, b_{2,2}^{(1)}, b_{1,3}^{(2)}, b_{2,3}^{(2)}, b_{1,4}^{(G)}, b_{2,4}^{(G)}]^T \quad (11)$$

is data bit sequence, signal power is given by

$$W = \text{diag}[\sqrt{W_{1,1}^{(1)}}, \sqrt{W_{1,1}^{(2)}}, \sqrt{W_{1,1}^{(3)}}, \sqrt{W_{1,1}^{(4)}}, \sqrt{W_{1,1}^{(5)}}, \sqrt{W_{1,1}^{(6)}}, \sqrt{W_{1,1}^{(7)}}, \sqrt{W_{1,1}^{(8)}}]$$

(12)

fading matrix is given by

$$C = \begin{pmatrix} \alpha_{1,1} & 0 & \alpha_{1,2} \\ 0 & \alpha_{1,2} & 0 \\ \alpha_{1,1} & \alpha_{1,2} & \alpha_{1,2} \end{pmatrix} \quad (13)$$

the cross correlation matrix of normalized signature waveform is given by,

$$C = \begin{pmatrix} \Gamma_{1,1} & \Gamma_{1,2} & K & \Gamma_{1,3}^{(1)} & \Gamma_{1,4}^{(1)} & A & \Gamma_{1,5}^{(1)} & \Gamma_{1,6}^{(1)} & A & \Gamma_{1,7}^{(1)} & \Gamma_{1,8}^{(1)} & M \end{pmatrix}$$

(14)

where, and $n_i$ is Gaussian zero mean $K$ vector with covariance matrix equal to $\sigma_i^2 I^d$. 

- 34 -
The matched filter outputs pass through the decorrelating filter to reduce MAI by matrix inversion. The output of the decorrelating filter for the $i$th subband carrier branch, it is assumed that "$i$th user" can mean either high rate user data or low rate user data, is given by

$$ Y_i = W^{-1}y_i = WCb_n + n_y, $$

where the noise vector $n_y$ is Gaussian zero-mean with covariance matrix $\sigma_n^2R^{-1}$.

From [1], the probability of the $k$th the user is obtained as

$$ P_k = \int_0^\infty Q\left(\sqrt{\frac{w_k\gamma}{(\Gamma-1)_{\text{KK}}}}f_y(\gamma)\right)\,d\gamma, $$

where $Q(x) = \frac{1}{\sqrt{2\pi}}\int_x^\infty e^{-\frac{t^2}{2}}dt$.

From [1], $\gamma$ and the p.d.f of $\gamma$ is given by

$$ \gamma = \sum_{j=1}^M |\alpha_{k,j}|^2/\sigma_j^2, $$

$$ f_y(\gamma) = F^{-1}\{\Phi_y(s)\}, $$

where, $\alpha$ is i.i.d Rayleigh random variable and $\Phi_y(s)$ is the moment-generating function of $\gamma$.

$$ \Phi_y(s) = \prod_{j=1}^L \frac{\sigma_j^2}{s + \sigma_j^2}. $$

IV. Simulation

In this section, for simulation example, the number of low rate users are $L = 4$ and high rate users are $H = 1$. In fig. 3, BER of the proposed detector and the conventional single rate decorrelating detector are compared under a frequency selective Rayleigh fading channel. The proposed multirate decorrelating detector as a equivalent performance to conventional single rate decorrelating detector.

It verify that the proposed decorrelating detector can be used at multirate transmission systems. In this simulation, a 4 rate user who has a 4 times spreading code as fast as basic rate user has 4 virtual users.
rate data and high rate data.

![Graph](image)

그림 5. 저속 데이터 전송률과 고속 데이터 전송률의 비트오류 확률

Fig. 5. Bit error probability of low rate data and high rate data.

In fig. 5, BER of low rate data and high rate data is compared under the same rate and same the number of users. The high rate users data have more bad influence than low rate users data when they are transmitted simultaneously.

V. Conclusions

The new multirate decorrelating detector combining multicharrier CDMA was proposed and analyzed in term of BER performance in a frequency selective Rayleigh fading channel. The proposed multirate decorrelating detector has equivalent system performance to single rate decorrelating detector. So, the proposed decorrelating detector can be considered as promising a multirate multi users detection scheme. But when the gap of the rate between low rate data and high rate data is increased, there is a problem which the complexity of the decorrelating detector also increased. The one of the future works of this research can solve this problem.
