#### Abstract

The crystal structure of $\mathrm{K}_{3} \mathrm{Na}_{2}\left[\mathrm{SbW}_{6} \mathrm{O}_{34}\right] \cdot 12 \mathrm{H}_{2} \mathrm{O}$ has been determined. Final $\mathrm{R}=0.081$ for 890 observed independent reflections collected by diffractometry. Crystal data as follows: trigonal, space group R3̇m, $a=9.794(1) \AA, a=84.72(1)^{\circ}, Z=1$. The heteropolyanion has a structure with point symmetry $\mathrm{D}_{3}(\overline{3} \mathrm{~m})$, of the ideal Anderson-type heteropolyanion. The $\mathrm{Sb}-\mathrm{W}$ and W - W distances are $3.259(2)$ and $3.259(3) \AA$. Three types of $\mathrm{W}-\mathrm{O}\left(\mathrm{W} \cdot \mathrm{O}_{1}, \mathrm{~W}-\mathrm{O}_{\Delta}\right.$ and $\mathrm{W} \cdot \mathrm{O}$ ) distances are 1.7312$), 1.95(4)$ and $2.20(3) \dot{A}$. The $\mathrm{Sb}-\mathrm{O}$ distance is $1.97(3) \dot{\mathrm{A}}$.

## Introduction

The Anderson-type' heteropolyanion is typical $\mathrm{XM}_{6}$ (X:heteroatom, M: Mo and W) heteropolyoxometalate species having $D_{3 d}$ point symmetry. The structural studies of Anderson-type hexamolybdoheteropolyanions such as $\left[\mathrm{TeMo}_{6} \mathrm{O}_{24}\right]^{6-2},\left[\mathrm{TMO}_{6} \mathrm{O}_{24}\right]^{5-3},\left[\mathrm{H}_{6} \mathrm{CrMo}_{6} \mathrm{O}_{24}\right]^{-4},\left[\mathrm{H}_{6} \mathrm{CoMO}_{6} \mathrm{O}_{24}\right]^{3-5}$, $\left[\mathrm{H}_{4.5} \mathrm{P}_{4} \mathrm{O}_{6} \mathrm{O}_{24}\right]^{3 .-6}$ and hexatungstoheteropolyanions such as $\left[\mathrm{MnW}_{6} \mathrm{O}_{24}\right]^{8-7},\left[\mathrm{PtW}_{6} \mathrm{O}_{24}\right]^{8}$ and $\left[\mathrm{H}_{3} \mathrm{PtW}_{6} \mathrm{O}_{29}\right]^{-9}$ polyanions had been reported. These Anderson-type structures consist of central $\mathrm{XO}_{6}$ octahedron with six $\mathrm{MO}_{6}$ octahedra surrounding it on a plane always sharing their edges. However, the hexamolybdoantimonate( V ) polyanion, $\left[\mathrm{H}_{2} \mathrm{SbMO}_{6} \mathrm{O}_{2}\right]^{5-10}$ has the bent structure with $\mathrm{C}_{2 v}$ ( 2 mm ) point symmetry. This heteropolyanion has the same framework as the $\left[\mathrm{Mo}_{2} \mathrm{O}_{2}\right]^{6-14}$ and $\left[\mathrm{H}_{4} \mathrm{PtMo}_{6} \mathrm{O}_{24}\right]^{4.6}$ polyanions. We report in this paper the structure of the $\left[\mathrm{SbW}_{6} \mathrm{O}_{84}\right]^{7}$. polyanion which is the ideal Anderson-type heteropolyanion.

## Experimental

The title compound was prepared by mixing $\mathrm{K}\left[\mathrm{Sb}(\mathrm{OH})_{6}\right]$ and $\mathrm{K}_{2} \mathrm{WO}$, solutions (adding a small portion of NaCl ) in the

[^0]molar ratio of $\mathrm{Sb}: \mathrm{W}=1: 6$, adjusting the pH to 5.4 with dilute $\mathrm{HNO}_{3}$ solution. After concentrating on the water bath, filtering and cooling at room temperature, colourless, transparent rectangular crystals of $\mathrm{K}_{5} \mathrm{Na}_{2}\left[\mathrm{SbW}_{6} \mathrm{O}_{24}\right] \cdot 12 \mathrm{H}_{2} \mathrm{O}$ were separated from the solution. A summary of crystal data, together with the details concerning intensity measurements. is given in Table 1. Intensities of standard reflections remained constant throughout data collection. The structure was solved by heavy-atom method; Sb and W atoms were located from three-dimensional Patterson maps, remaining atoms from successive difference Fourier maps; structure refined by blockdiagonal least squares based on F with anisotropic thermal parameters for all atoms; atomic scattering factors from $I n$ termational Tables for $X$-ray Cystallography ${ }^{12}$ including f ' and $\mathrm{f}^{\prime \prime}$ for Sb and W . Calculations carried out with UNICS $/ I^{10}$ on the HITAC M-280H computer at the Computer Center of the University of Tokyo. The final atomic parameters are given in Table 2.*

## Discussion

The $\left\{\mathrm{SbW}_{6} \mathrm{O}_{24}\right]^{-}$polyanion has $\mathrm{D}_{34}(3 \mathrm{~m})$ symmetry. It is isostructural with the ideal Anderson-type heteropolytungstate anions such as $\left[\mathrm{MnW}_{6} \mathrm{O}_{24}\right]^{5-6}$ and $\left[\mathrm{PtW} \mathrm{O}_{6} \mathrm{O}_{24}\right]^{8.7}$. Figure 1 shows the crystal structure projected on the (111) plane. In this figure, there are several overlaps between the atoms such as $\mathrm{Na}-\mathrm{Sb}-\mathrm{Na}, \mathrm{Aq} 2-\mathrm{Oc}-\mathrm{Aq} 1$ and $\mathrm{K}-\mathrm{Ob}$. The W atoms are located

at the corners of the regular hexagon and the Sb atom is located at its center. All the Sb and W atoms are octahedrally surrounded by the $O$ atoms. This heteropolyanion has three types of O atoms, denoted $\mathrm{O}_{1}, \mathrm{O}_{s}$ and $\mathrm{O}_{c}$, where $\mathrm{O}_{\text {, is }}$ the terminal O atom bound to a W atom, Ob is the bridging atom between two W atoms, and $\mathrm{O}_{c}$ is the central atom coordinated to the Sb and W atoms. The $\mathrm{W}\left(\mathrm{O}_{b}\right)_{2}\left(\mathrm{O}_{c}\right)_{2}\left(\mathrm{O}_{1}\right)_{2}$ octahedra are joined to the central $\mathrm{Sb}\left(\mathrm{O}_{6}\right)_{6}$ octahedron by edge sharing. In-

teratomic distances and angles of the polyanion are listed in Table 3. The molecular dimensions of the $\left[\mathrm{SbW}_{6} \mathrm{O}_{24}\right]^{7-}$ polyanion agree well with those of the isostructural $\left[\mathrm{MnW} \mathrm{O}_{6} \mathrm{O}_{24}\right]^{0.6}$ and $\left[\mathrm{PtW} \mathrm{W}_{4} \mathrm{O}_{24}\right]^{3-7}$ polyanions, except small variations caused by the different ionic radii and charges of the heteroatoms.

During the course of the refinement, the temperature factor of the K atom was found to be larger than the ordinary value. Although the multiplicity of the $K$ atoms coordination ( $x, x, z$ ) is $6 / 12$ in the $R 3$ m space group, a reasonable temperature factor was obtained by reducing occupancy factor of K to $5 / 6$. The elemental analysis data of K (calc. : $9.4 \%$, found: $10.0 \%$ ) also support this occupency factor. Thus, we established the correct stoichiometry as $\mathrm{K}_{5} \mathrm{Na}_{2}$ [ $\mathrm{SbW} \mathbf{6}_{6}$ $\left.\mathrm{O}_{14}\right] \cdot 12 \mathrm{H}_{2} \mathrm{O}$ assuming that five $\mathrm{K}^{+}$ions randomly occupy the six positions. Figure 2 shows the possible hydrogen bonds and the coordination features of $\mathrm{Na}^{+}$and $\mathrm{K}^{+}$ions in the

crystal. The $\mathrm{Na}^{*}$ ion is coordinated octahedrally by six water
molecules as $\left[\mathrm{Na}(\mathrm{Aq} 1)_{3}(\mathrm{Aq} 2)_{3}\right]^{+}$. The $\mathrm{K}^{*}$ ion is comrdinated to eight oxygen atoms as $\left[\mathrm{K}(\mathrm{Aq} 1)_{2}(\mathrm{Aq} 2)\left(\mathrm{O}_{t}\right)\left(\mathrm{O}_{7}\right)_{4}\right]^{+}$. The $\left[\mathrm{K}_{3} \mathrm{Na}-\right.$ (Aq) $)^{4+}$ cluster with 3 mm point symmetry are placed at all of the tetrahedral cavities in the anionic packing. The $\mathrm{Na}^{+}-\mathrm{O}$ and $\mathrm{K}^{+}-\mathrm{O}$ distances less than $3.2 \AA$ are given in Table 4. All water molecules form hydrogen bonds with the oxygen atoms in the polyanions. The distances of $\mathrm{Aq} 1-\mathrm{O}_{b}$ are 2.91 (7) and $2.68(6) \AA$ (adjacent layer anion) and the Aq2-O, distance is 2.95 (4) $\AA$ (two different anions in the adjacent layer). The heteropolyanions are joined to one another through the water molecules and the $K^{*}$ ions.
