( ), labels of the heme methyl signals in the text and hi', the heme numbering according to the order of the major reduction.
$2-\mathrm{CH}_{3}$ of heme $3(\mathrm{~J})$. The TOCSY connectivity of the last propionate is shown in Figure 3.

From NOESY cross peaks, the heme methyl group in the proximity (signal N) could be identified (Figure 3). On irradiation at signal N, an NOE signal was observed at signal $O$ (the spectrum is not shown). Since the second nearest heme methyl group from $2-\mathrm{CH}_{3}$ of heme $2(\mathrm{O})$ is that at $\mathrm{C}-18$ of heme 2, signal N can be assigned to it. This was confirmed by an NOESY cross between the $\beta$ proton of 17 propionate of heme 2 and His67 $\mathrm{C}_{4} \mathrm{H}$, the interproton distance of which is 0.326 nm according to the crystal structure. Now, signal $L$ is the only one left and should be ascribed to $7-\mathrm{CH}_{3}$ of heme 3. The assignment could be carried out consistently just by moving signal J from h3' to $\mathrm{h} 4^{\prime}$. The assignments of heme methyl groups and propionate groups were summarized in Table 1.

The heme assignment was revised for hemes 2 and 3 (se-
quential heme number). Our next target is to elucidate the structural factors which determine the redox potentials of each of the four hemes on the basis of the assignments established in this work.

## Intramolecular Hydrodimerization of Activated Dienes Mediated by Magnesium in Methanol

Ge Hyeong Lee, Hyeon Kyu Lee, Eun Bok Choi, and Chwang Siek Pak*<br>Korea Research Institute of Chemical Technology. P.O. Box 107, Yusung, Taejon 305-606, Korea

Received August 16, 1995

It has been reported that the electrochemical hydrodimerization of $\alpha, \beta$-unsaturated ketones, esters, and nitriles proceeds via anion radicals in aprotic media in the absence of metal cations, and allyl radicals in protic media, respectively. ${ }^{1}$ As previously noted for sequential C-C bond formation via one electron transfer, methods for intramolecular $\beta$-coupling reaction of activated olefins have been limited to electrochemical hydrodimerization and $\mathrm{n}-\mathrm{Bu}_{3} \mathrm{SnH}^{2}$ Recently, it has been reported that intramolecular cyclization of activated dienes with magnesium metal in methanol at room temperature proceeds smoothly. ${ }^{3}$ we proposed that reactions proceed via allyl radical intermediate resulting from one electron transfer to activated olefins followed by protonation of anion radicals in the presnece of proton donor, methanol. ${ }^{4}$

Here we report that intramolecular hydrodimerization of

${ }^{\text {a }}$ Substrates were prepared from the reaction of $25 \%$ glutaraldehyde with the corresponding triphenylphosphorylidenes in methanol at $50{ }^{\circ} \mathrm{C}$ followed by the separation with the silica gel column chromatography. ${ }^{\text {A }}$ Isomeric mixture. 't and $\mathbf{c}$ designates trans and cis relationships between the functional group appendage when cyclized, and $s$ designates the simple reduction product not cyclized. ${ }^{d}$ Cis and trans designate cis and trans relationship between 1-H and 2-acetyl group in bicyclic products, respectively. ${ }^{d}$ Ratios were determined by $500 \mathrm{MHz}{ }^{1} \mathrm{H}$ NMR.

Figure 1.
activated bisolefins proceeds via stepwise irreversible 1,4 -addition of allyl radical resulting from one electron transfer to an activated olefins to afford substituted cyclopentane rings (Table 1). When geometric isomers of bisolefins activated with ketone group (1A, 1B, and 1C) were treated with 3 equiv magnesium powder in absolute methanol at -43 ${ }^{\circ} \mathrm{C}$ in the presence of a catalytic amount of mercuric chloride, a trans product $1 t$ and cyclized products ( 1 c -cis and 1 c -trans) derived from the cis product 1c, presumably via 1,4 -addition of ally radical intermediate was obtained in $94 \%$ yield. Regardless of the configuration of carbon-carbon double bond the major product was trans isomer. It might be mostly due to the steric hindrance caused by the vicinal appendage (acetyl group) in the course of cyclopentane ring formation. It is noteworthy that the trans/cis product ratio from 1B and 1C was approximately the same, on the other hand the ratio

Figure 2.
from 1A was twice as high as the other two. It can be explained considering that once an electron is transferred to either Z-enone part of $\mathbf{1 B}$, which is preferred electron acceptor to the corresponding E-enone part, ${ }^{\text {la }}$ or E-enone part of 1C at C -2 atoms, rapid thermodynamic equilibrium occurs before the cyclization step takes places due to the low rotation barrier of $\mathrm{C}_{2}-\mathrm{C}_{3}$ bond of allyl radical to give the identical equilibrium mixture with s-trans configuration as a major.

In the case of $1 A$, while the configuration of the allyl radical part resulting from an electron transfer to $Z$-enone part followed by protonation of the anion radical with methanol is the same as that of 1B and 1C, the configuration of remaining Z-enone part is different from E-enone part of 1B and 1C. Such a configurational difference of allyl radical acceptor plays a crucial role in determining stereochemistry of cyclopentane ring (Figure 1).
Since the steric repulsion between acetyl group in endo position and cyclopentane ring in allyl radical intermediate 4 is severer compared to that between the acetyl group in exo position and the cyclopentane ring in the allyl radical intermediate 5, stereoselectivity of trans and cis products seems to be larger in 1A than in 1B and 1C. Simutaneous aldol condensation of the cis product 1c under the basic media, $\mathrm{Mg}(\mathrm{OMe})_{2}$, affords stereoisomeric [3.3.0]bicyclic products, 1 c -cis and lc-trans (Figure 2). When the aldol condensation takes place, the transition state $\mathbf{1 c ^ { \prime }}$ is more stable than the transition state $1 \mathbf{c}^{\prime \prime}$ so that le-cis was obtained as a major product. Although $1 c^{\prime}$ is sterically less favorable than $1 \mathbf{c}^{\prime \prime}$ due to the steric hindrance between $\mathrm{H}-4$ atom and acetyl group, electronically $\mathbf{1 c}$ ' is more favorable than $\mathbf{1 \mathbf { c } ^ { \prime \prime }}$. As a result, electronic effect prevails in determining the stereochemistry of the products. ${ }^{\text {a }}$

And the steric hindrance between the methyl group and the pentane ring gives the cis relationship between $1-\mathrm{H}$ atom and $3-\mathrm{CH}_{3}$ group. Stereochemistry of $\mathbf{1 c}$-cis and $1 \mathrm{c}-$ trans was determined by analysis of 600 MHz NOESY spectrum. ${ }^{5}$ In contrast to the $\mathrm{Mg} / \mathrm{MeOH}$ case, when ic was treated with $\mathrm{n}-\mathrm{Bu}_{3} \mathrm{SnH}$ a single bicyclic isomer 6 of the trans relationship between $1-\mathrm{H}$ and $3-\mathrm{CH}_{3}$ and 1 lt was obtained in the ratio of $1: 3.5^{2 \mathrm{a}}$

In the case of bisolefins 2 where ester group was attached as an activating group, similar stereochemical trends were observed. However, higher stereoselectivity (trans/cis : 15/1) was attained for 2A compared to 2B and 2C. Interestingly, bisolefin 1 did not give any simple reduction product at all, whereas bisolefins 2 and 3 gave the simple reduction products ( 2 s and 3 s ) in $25 \%$ and $60 \%$ yields, respectively. The similiar result was observed when the $\alpha, \beta$-unsaturated

## Communications to the Editor

nitrile group tethered to the ketone was cyclized with magnesium metal in absolute methanol, a large amount of saturated product was obtained. ${ }^{4 a}$ In an attempt to trap a radical intermediate, an $\alpha, \beta$-unsaturated ketone tethered to a good radical acceptor as shown below was subjected to the same reaction condition as above, however, we only obtained the simple reduction product in quantitative yield instead of the expected 5 -exo-trig. cyclized product.

Although the mechanistic explanation of magnesium in methanol had been suggested to proceed through the $\beta$-coupling of radical anion intermediate, ${ }^{6}$ exact mechanism is needed to be defined further.

## A Convenient Method for the Preparation of Ni triles and Carbodiimides Using N-Methyl-2-Pyridinecarbamoyl Chloride

Jae In Lee

Department of Chemistry, College of Natural Science,<br>Duksung Women's University,<br>Seoul 132-714, Korea

Received August 31, 1995

In connection with our study on the synthetic utility of active carbamoyi choride, we have reported that N -methyl-2-pyridinecarbamoyl chloride is an efficient coupling reagent of carboxylic acids. ${ }^{1}$ We now wish to report that nitriles can be prepared from aldoximes in high yields and thioureas are cleanly converted into the corresponding carbodiimides using $N$-methyl-2-pyridinecarbamoyl chloride.
$N$-Methyl-2-pyridinecarbamoyl chloride was new conveniently prepared by addition of an equimolar solution of 2 (methylamino)pyridine and triethylamine in methylene chloride to a solution of one-third equivalent of bis(trichloromethyl)carbonate("triphosgene"). ${ }^{2}$ a crystalline, stable solid, in methylene chloride at $0^{\circ} \mathrm{C}$ (eq. 1).

(eq. 2)
