Formation of *o*-/*p*-Quinomethanes and *p*-Quinodimethanes from the Photoaddition of Diphenylacetylene to *o*-Quinones[†]

Ae Rhan Kim, Yoon Jung Mah, and Sung Sik Kim*

Department of Chemistry, Chonbuk National University, Chonju 561-756, Korea

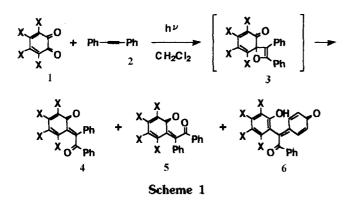

Quinones are an important class of compounds as quinone dye-stuffs in industry or dehydrating agents in organic synthesis in addition to a vital role in biological systems. Due to their various spectroscopic properties, the photochemistry of quinones has been a subject of interest in many areas.¹² Our interest in diverse reactivity of excited quinones has promoted us to investigate the type of the photoadducts of quinones.³⁻⁶ Bryce-Smith *et al.* have reported that tetrachloro-1,2-benzoquinone 1a reacts photochemically with diphenylacetylene (DPA) 2 to give dioxenes.⁶ Photoreaction of 1a and 2 in acetone or acetonitrile at >400 nm gave 1:2 adduct as 1,4-dioxene. We found that, when irradiated with 300 nm UV light, *o*-quinones add to 2 to give two isomeric *o*-quinomethanes, *i.e.*, 4 and 5, 8 and 9, and 12 and 13, *via* spiro-oxetene intermediates, like 3.⁷

Recently, we found an interesting fact that irradiation (300 nm) of tetrahalo-1,2-benzoquinones 1 and DPA 2 in dichloromethane gave new type of p-quinomethanes 6, as well as two isomeric o-quinomethanes, 4 and 5, as shown in Scheme 1. Preparative photochemical reactions were conducted in a photoreactor composed of a water-cooled system and a Pyrex reaction vessel with 300 nm UV lamps (Rayonet Photochemical Reactor, Model RPR-208), after purging with nitrogen gas (purity; 99.9%) for 30 min. The photoproducts were isolated by flash column chromatography (silica gel, 230-400 mesh, Merck Co.) using *n*-hexane and ethyl acetate as the eluents (from 97:3 to 9:1, v/v).

Irradiation of a dichloromethane solution (100 mL) of tetrachloro-1,2-benzoquinone 1a (246 mg, 1.0 mmol) and DPA 2 (178 mg, 1.0 mmol) with 300 nm UV light for 24 h afforded not only two isomeric *o*-quinomethanes, 4a (26%) and 5a (28%), via unstable spiro-oxetene 3a, but also a novel *p*-quinomethane 6a (17%).⁸ The absorption peaks for

[†]This paper is dedicated to Professor Sang Chul Shim on the occasion of his 60th birthday.

1296 Bull. Korean Chem. Soc. 1998, Vol. 19, No. 12

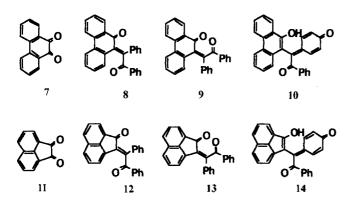

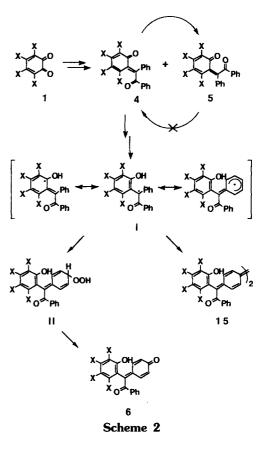

the four protons of quinone moiety in **6a** were observed at δ 7.57, 7.49, 7.10, and 6.91 as doublets (*J*=8.0 Hz) each in ¹H NMR spectrum (CDCl₃).

Irradiation of tetrabromo-1,2-benzoquinone 1b (424 mg, 1.0 mmol) and DPA 2 (178 mg, 1.0 mmol) in dichloromethane (100 mL) with 300 nm UV light for 24 h yielded same types of quinomethanes, 4b, 5b, and 6b, in 29%, 30%, and 23% yields, respectively.⁹ Two dimensional ¹H-¹H correlation spectrum (CDCl₃) of 6b shows that the proton peaks of quinone moiety at δ 7.09 and 6.90 correspond to the peaks at δ 7.56 and 7.48, respectively.

It has been known that phenanthrenequinone 7 adds photochemically to alkynes to yield 1,4-dioxene, quinomethane, or 1,3-dioxole.^{10,11} Irradiation of phenanthrenequinone 7 (208 mg, 1.0 mmol) and DPA 2 (89 mg, 0.5 mmol) in dichloromethane (200 mL) with 300 nm UV light for 48 h afforded a *p*-quinomethane 10 (26%), as well as two isomeric *o*quinomethanes, 8 (27%) and 9 (29%).¹² The formation of 8 (or 9) and 10 was confirmed from the mass spectra (EI), in which the molecular ions were found at m/e 386 and 402, respectively. Two dimensional ¹H-¹H correlation spectrum (CDCl₃) of 10 showed that the four absorption peaks of quinone moiety at δ 7.57 and 7.47 correspond to the peaks at δ 7.09 and 6.90, respectively. Two carbon peaks of 10 were observed at δ 207.0 and 205.5 in ¹³C NMR spectrum (CDCl₃).

Irradiation of acenaphthenequinone 11 (91 mg, 0.5 mmol) and DPA 2 (89 mg, 0.5 mmol) in dichloromethane (200 mL) with 300 nm UV light for 48 h gave a *p*-quinomethane 14 (19%), as well as two isomeric *o*-quinomethanes, 12 (24%) and 13 (26%).¹³ The exact structure of *o*-quinomethanes, such as 8, 9, 12, and 13, was also confirmed by irradiating in dichloromethane in the presence of molecular oxygen, in

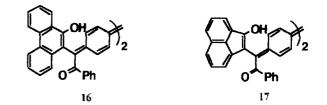

which two benzene rings in the molecules was fused to give the corresponding oxidative photocyclization products. Purified 8 (or 12) was irradiated with 300 nm UV light in dichloromethane to give 10 (or 14). Irradiation of the other isomer 9 (or 13) also gave rise to 10 (or 14). Two dimensional ¹H-¹H correlation spectrum (CDCl₃) of 14 showed that the peaks at δ 7.58 and 7.40 correspond to the peaks at δ 7.06 and 6.80, respectively. Mass spectrum (EI) showed the molecular ion peak at m/e 376.

In order to elucidate the formation mechanism of 6a, a dichloromethane solution of 4a was purged with molecular oxygen for 30 min and irradiated in dichloromethane to give 6a. Irradiation of 4 after degassing with freeze-pump-thaw method did not give 6.

These results imply that the formation of p-quinomethane 6 proceeds via triplet state of the starting material 4. It may be considered that irradiation of 4 leads to the formation of radical intermediate I, as shown in Scheme 2. The resonance-stabilized radical I can be alive until a molecular oxygen is added to give hydroperoxide II. The hydroperoxide II may be considered to decompose to yield the final product 6 as a novel p-quinomethane.

Irradiation of 1 and 2 in high concentration also gave rise to Chichibabin hydrocarbons 15 as a dimeric *p*-quinodimethane. The FAB mass spectrum of 15 (X=Cl) showed the molecular ion peak at m/e 845 (M+H). ¹H NMR spectrum (CDCl₃) showed hydroxyl protons and aromatic protons at δ 11.40 (s) and 7.99-7.59. The proton signals of *p*-quinodimethane moiety were observed at δ 7.57, 7.49, 7.10, and 6.91, in which all signals appeared as doublet (*J*=8.0 Hz) each. The same type of dimeric compounds, *i.e.*, 16 and 17, were also observed and isolated from the photoreaction of 2 and 7 (or 11), as shown below.^{14,15}

Interestingly, one-way E-to-Z isomerization was observed between the two o-quinodimethanes, 4 and 5.⁷ Irradiation of 20 mg (4.7×10^{-5} mol) of E-isomer 4a in 15 mL of dichloromethane with 300 nm UV light for 24 h gave Zisomer 5a (23%), and also 6a (16%), whereas irradiation of 5a did not give 4a. The similar results were obtained in the case of 8 and 12.

In conclusion, we have shown here that two isomeric o-quinomethanes are produced when o-quinones and DPA 2 are irradiated with 300 nm UV light, instead of visible light (>400 nm). It is also interesting to note that novel p-quinomethanes and p-quinodimethanes may be formed via the initially produced o-quinomethanes.

Extension of the chemical properties of various oquinones and their photoproducts will be investigated.
