# Synthesis of Unusual Rhenium Complexes with Schiff Bases 

Jung Young Kim, Yong Jun Ji, Hyun-Joon Ha, and Hee K. Chae<br>Deparment of Chemishy, Hanhow University of Foreign Studies, Hongin 49-791, Korea Received December 28, 2002

Key Words: I'hosphine oxide. Rhenium. Schiff base

Schiff bases offer a versatile and flexible series of ligands capable to bind with various metal ions to give compleses with suitable properties for theoretical and/or practical applications. Since Wilkinson published Schiff-base complexes in 1979. a large number of polydentate Schiff-base compounds have been structurally characterized and extensively explored for the developinent of technetium and renium chemistry with radiophammaceutical applications. ${ }^{-}$Rescarch has been focused on the chemistry of (O.N.S)-tetradendate. at first. and later tridentate or bidentate Schiff-base complexes of Re and Tc .

Schiff bases generated by condensing 2-aminophenol with salicylaldelsede could act as a model of multidentate ligands towards rhenium and technetium cores. ${ }^{3}$ Especially. 2(salicylidencamino)bentencthiol (SNO. S-phsalH ${ }_{2}$ ) is not the stable form of this noncoordinated molecule. white 2-(2lịdroxyphentli)phenol (ONO. ()-phsalH2) is stable. ${ }^{-1} \mathrm{At}$ room temperature the S -phsalH ${ }_{2}$ Schiff base comerts to 2 -(2-hydroxyphenyl)benzencthia\%oline (hbiH) by an intramolecular ring closing reaction. which also comerts to 2-(2lydroxyphenvl)benenethiazole (hbt) by an oxidatise photochemical aromatization reaction as illustrated in Figure 1. Several oxometal complexes of s-plsalH ${ }_{2} / \mathrm{hb}_{2} \mathrm{H} / \mathrm{hbt}$ have extensively been studied ${ }^{1.5}$ In the case of $2-(2-p y r i d y l)-$ benzolhiazoline. similar tautomerization of the ligand has been reported but only one tautomer exists in the solid statc. ${ }^{45}$ Howerer. attempt to isolate these Schiff base rheniun and technetium complexes with both of the tautomer S ,plisalH2/hbıH/hbi ligands have been unsuccessful. Here. we demonstrate reactions of these [SNO] and [ONO] Schiff
bases with $\operatorname{Re}(V)$ ions and interactions among the $S$ phsalH $H_{y} / \mathrm{hbtH} / \mathrm{hbt}$ ring tautomers. The erystal structures of the $\mathrm{Re}(\mathrm{O})\left(\mathrm{S}_{-}\right.$-phsal)(hb1) and $\mathrm{ReCl}_{2}\left(()\right.$-phsal) $\left(\mathrm{OPPl}_{3}\right)$ are described. respectively.

The [SNO] complex $\left[\mathrm{RcO}\left(\eta^{3}-S-\right.\right.$-phsal $)\left(\eta^{2}-h b t\right)$ (1) and the [ONO] complex $\left[\mathrm{ReCl}_{2}\left(\mathrm{OPPl}_{3}\right)\left(\eta^{3}-()\right.\right.$-phsal $\left.)\right]$ (2) were oblained from reaction of $\left[\mathrm{B} \neq \mathrm{Et}_{3} \mathrm{~N}\right]\left(\mathrm{RcOCl}_{4}\right)$ with . S'phsalH ${ }_{2}$ at room temperature and $t-\mathrm{RcOCl}_{3}\left(\mathrm{PPh}_{3}\right)_{2}$ with O-phsalH ${ }_{2}$ on heating. respectively. These complexes were characterized by elemental analyses. spectroscopic methods and X-ray crystallography.

The crystallographic analysis of $\mathbf{1}$ shows the presence of a neutral oxorhenium( $V$ ) comples in which the overall geometry around the central rhenium atom is best described as a distorted octahedron: the $\mathrm{S} . \mathrm{N}$ and O atoms of the tridentate [SNO] ligand form in a mer-coordination. and the O and N atoms of the hbt ligand bind bidentately as depieted in Figure 2. The $\mathrm{Rc}=\mathrm{O}$. Rc-S. Re-O and $\mathrm{Rc}-\mathrm{N}$ bond lengths are in the ranges observed for analogous compounds. The Re-S(1) bond distance of 2.311 (2) A is longer than those of $\mathrm{Rc}-\mathrm{O}(1)(2.075(6) \mathrm{A})$ and $\mathrm{Rc}-\mathrm{N}(1)(2.082(6) \mathrm{A})$ on the equitorial planc. and that of $\mathrm{Re}-\mathrm{O}(2)(1.96 .3(6) \mathrm{A})$ on the axial position. showing that the structural trans influence of the oxo group is not transmitted to oxygen atom. The most striking feature of the crystal structure of $\mathbf{1}$ is the bidentate binding of the libt rather than the tridentate one of Hhbt. This is clealy seen from the formation of the thiazole: whe difference of the distance between $\mathrm{C}(1+)$ and $N(2): 1.318(11) \AA$ ws. $1.333(9)$ A for $\mathrm{C}(1)-\mathrm{N}(1)$ single bond of the $\operatorname{s}$-phsal ligand. The $\mathrm{C}=\mathrm{N}$ distances of hbt

Figure 1. Schematic diagram of tautomerization between $2(2$-hydroxyphengl)henzenethol ( $S$-phsalHz) and $2(2$-hydroxyphenvl) benzenethiazoline (hbtH), and conversion to 2(2-lydroxy phenyl) benzentethiazole (hat)

Figure 2. ORTEP drawing of $\left[\operatorname{ReO}\left(\eta^{3}-S-p h s a l\right)\left(h^{2}-h b t\right)(1)\right.$. Selected bond lengths $(\lambda)$ and angles ( ${ }^{\prime \prime}$ ): $\operatorname{Re}(1)-O(1), 2.075(6) ; \operatorname{Re}(1)-O(2)$, $1.963(6)$ : $\mathrm{Re}(1)-\mathrm{O}(3) .1 .677(6): \mathrm{Re}(1)-\mathrm{N}(1), 2.082(6)$ : $\mathrm{Re}(1)-\mathrm{N}(2), 2.160(7)$ : $\mathrm{Re}(1)-\mathrm{S}(1), 2.311(2): \mathrm{N}(1)-\mathrm{C}(1), 1.333(9): \mathrm{N}(2)-\mathrm{C}(14)$, $1.318(11): \mathrm{N}(1)-\mathrm{Re}(1)-\mathrm{N}(2), 166.7(3): O(1)-\mathrm{Re}(1)-\mathrm{S}(1), 170.56(17) . O(2)-\mathrm{Re}(1)-\mathrm{O}(3), 166.8(2)$

 $1.987(3): \operatorname{Re}(1)-O(3), 2.027(3): \operatorname{Re}(1)-N(1), 2.063(4): \operatorname{Re}(1)-\mathrm{Cl}(1), 2.3362(11): \operatorname{Re}(1)-\mathrm{Cl}(2), 2.3542(10): \mathrm{N}(1)-\mathrm{C}(1), 1.281(6): \mathrm{N}(1)-\operatorname{Re}(1)-$ $O(3), 166.7(3): O(1)-\operatorname{Re}(1)-O(2), 172.54(1.3), \mathrm{Cl}(1)-\operatorname{Re}(1)-\mathrm{Cl}(2), 177.69(4)$
have been reported: $1.332(10) \mathrm{A}$ for $\left[\mathrm{TcOCl}_{3}(\mathrm{hbt})\right]^{-}$.ll The average angle around $\mathrm{C}(14)$ is $120.0(4)^{\circ}$. that means $\mathrm{sp}^{2}$ hy brid.

The X-ray stnicture of $\mathbf{2}$ is shown in Figure 3. The rhenium is six-coordinate in a distorted octahedral coordination sphere: the $\mathrm{Cl}_{2}$ fragment is in trans arrangement and the $\mathrm{O}_{3}$ fragment is in a meridional coordination. The O and N atoms of the O-phsal ligand bind tridentately, and the distance between $\mathrm{C}(1)$ and $\mathrm{N}(1)$ of the ligand is $1.281(6) \mathrm{A}$. which means a $\mathrm{C}=\mathrm{N}$ bond. The feature of this structure is
based on the formation of triphenylphosphine oxide. and therefore the oxidation state of the rhenium is $+\downarrow$. In most of reactions of trichlorobis(triphenylphosphine)oxorhenium (V) the rhenium-oxygygen double bond is untouchable and remains. Limited studies have been available regarding rhenimm(IV) complexes with triphenylphosphine oxide. ${ }^{\text {. }}$ The nitrogen atom lies trans to $\mathrm{OPPh}_{3}$ oxygen and the value of $2.063(+)$ A for the $\mathrm{Re}-\mathrm{N}$ bond is found in the range $2.030(5)-2.091(6) \mathrm{A}$ for the other phosphine oxide Re complexes. ${ }^{\text {c }}$ This structural trans effect is not so strong
compared to that of $\operatorname{Re}(\mathrm{III})-\mathrm{PPh}_{3}$ due to weak back-bonding ability of $\operatorname{Re}(\mathrm{lV})$ to $\mathrm{OPPh}_{3}$.
