# 3-D Hydrogen-Bonded Frameworks of Two Metal Complexes with Chelidamic Acid: Syntheses, Structures and Magnetism 

<br>${ }^{\dagger}$ State Kev Laboratorv of Structural Chemistry, Fujan Institute of Research on the Structure of Matter, Chinese Academy of Sciences, Fuzhou. Fujian 350002, P. R. China<br>${ }^{\ddagger}$ Graduate School of Chinese Academv of Sciences. Beijing 100039, P. R. China<br>Received Februarv 13. 2004

#### Abstract

Complexes $\mathrm{M}\left(\mathrm{C}_{-} \mathrm{H}_{2} \mathrm{NO}_{5}\right) 3 \mathrm{H}_{2} \mathrm{O} \cdot \mathrm{H}_{2} \mathrm{O} \cdot 0.25 \mathrm{MeCN}(\mathrm{M}=\mathrm{Ni}$. Co ) were crystallized from the reactions of $\mathrm{Ni}\left(\mathrm{CH}_{3} \mathrm{COO}\right)_{2} \cdot 4 \mathrm{H}_{2} \mathrm{O}$ or $\mathrm{Co}\left(\mathrm{CH}_{3} \mathrm{COO}\right)_{2}-2 \mathrm{H}_{2} \mathrm{O}$ with KSCN and 2.6 -dicarboxy-4-hy dronypy ridine (chelidamic acid). The structures were characterized by X-ray crystallography. The crystal structures of $\mathbf{1}$ and 2 show a distorted octahedral coordination geometry around the $\mathrm{M}(\mathrm{II})$ ions. which are chelated by one nitrogen atom and two oxygen atoms of the chelidamic acid and three water molecules. Complexes $\mathbf{1}$ and $\mathbf{2}$ display the hydrogenbonded 3D framework. The magnetic behavior of $\mathbf{2}$ exhibits antiferromagnetic interaction.

Key Words: Crystal structures, Chelidamic acid, Antiferromagnetic interaction

## Introduction

Chelidamic acid ( $\mathrm{H}_{3} \mathrm{Chel}$ ) is used widely in biochemistry. organic chemistry. medical chemistry and even in HIV investigation. ${ }^{1-7}$ In addition, as an emblematical polydentate ligand, it was also of great interest in the study of coordination chemistry. Though the initial report of $\mathrm{H}_{3} \mathrm{Chel}$ was published in $1926{ }^{8}$ the crystal structure of the $\mathrm{H}_{3}$ Chel was not determined until $2000{ }^{5}$ In contrast. the studies concerning the transition metal complexes with chelidantic acid are rare. to our best knowledge, the only known examples consisting of $\mathrm{Cr}, \mathrm{Fe}, \mathrm{Sn}, \mathrm{Gd}, \mathrm{V}$ and Zn up to now. ${ }^{10-17}$ It is a good way to expand the chemistry of chelidamic acid and master its function or reaction conditions to research a variety of metal complexes with chelidanic acid.

The ain of this work is to report and extend the contribution on chelidamic acid chelating with other metal ions based on the syntheses. structures and properties of its cobalt(II). nickel(II) derivatives.

## Experimental Section

Materials and Physical Measurements. All reagents and solvents were purchased from conmercial sources and used without further purification. The IR spectra were recorded on a Nicolet Magna 750 FT-IR spectrometer with KBr pellets in the range $4000-400 \mathrm{~cm}^{-1}$. Elemental analyses ( C . H . and N ) were carried out on a Vario EL III elemental analyzer. TG analyses were performed on a Perkin-Elmer TGA7 instrument with a heating rate of $15 \mathrm{Kmin}^{-1}$. The magnetic susceptibility data were obtained using a Quantum Design PPMS6000 magnetometer. All data were corrected by the Pascal constants. ${ }^{21}$
Synthesis of Complex $1\left(\mathrm{Ni}\left(\mathrm{C}_{7} \mathrm{H}_{2} \mathrm{NO}_{6}\right) 3 \mathrm{H}_{2} \mathrm{O} \cdot \mathrm{H}_{2} \mathrm{O} \cdot 0.25\right.$ $\mathbf{M e C N})$. A mixture of $73 \mathrm{mg} \mathrm{Ni}\left(\mathrm{CH}_{3} \mathrm{COO}\right)_{2} \cdot 4 \mathrm{H}_{2} \mathrm{O}, 50 \mathrm{mg}$ $\mathrm{H}_{3} \mathrm{Chel}$ and 28 mg KSCN was dissolved in the 20 mL mixture solution of water and acetonitrile in a volume ratio
of $1: 1$. After dropping $1-2$ drops of KOH ( $1 \mathrm{~mol} / \mathrm{L}$ ). the resulting solution was refluxed with constant stirring for 2 hours. The solution was allowed to stand at room temperature. Green crystals of 1 were obtained over a period of 4 days. Elemental analysis (\%), Found (calcd): C. 28.15 (28.05); H. 3.28 (3.37): N, 5.52 (5.45). IR (KBr. $\mathrm{cm}^{-1}$ ). 3245 (vs). 2729 (m), 2617 (m), 2515 (m). 1605 (vs). 1466 (w), 1416 (s). 1389 ( vs ), 1331 (m), 1263 (m), 1057 (s). 939 (w), 872 (m). 808 (s). 744 (m), 702 (w), 580 (w). 521 (w). 444 (w).

Synthesis of Complex $2\left(\mathrm{Co}\left(\mathrm{C}_{7} \mathrm{H}_{2} \mathrm{NO}_{5}\right) 3 \mathrm{H}_{2} \mathrm{O} \cdot \mathrm{H}_{2} \mathrm{O} \cdot 0.25\right.$ MeCN). 2 was synthesized with $62 \mathrm{mg} \mathrm{Co}\left(\mathrm{CH}_{3} \mathrm{COO}_{2}\right)_{2} 2 \mathrm{H}_{2} \mathrm{O}$ in a similar way as for 1 . Deep red crystals of 2 were obtained over a period of 3 days. Elemental analysis (\%), Found (calcd): C, 28.10 (28.03): H. 3.32 (3.37): N, 5.49 (5.45). IR (KBr. $\mathrm{cm}^{-1}$ ). 3246 (vs), 2725 (m). 2617 (m), 2511 (m), 1603 (vs). 1464 (w), 1417 (s), 1387 (vs). 1336 (m), 1261 (m). 1049 (s). 941 (w). 872 (m). 806 (s), 744 (m), 703 (w), 579 (w). 513 (w). 444 (w).

X-ray Crystallography. Table 1 provides the summary of the crystal data. data collection, and refinement parameters for 1 and 2. Diffraction data were collected on a Rigaku Mercury CCD diffractometer for the present compounds with graphite-monocluromatic Mo $\mathrm{K} \alpha$ radiation $(\lambda=0.71073$ A) by the $\omega$ scan mode at 293 K . Empirical correction of absorption was applied for the two complexes. Both structures were solved by direct methods and refined anisotropically by full-matrix least squares based on $F^{2}$ for all the non-lydrogen atoms. For both of the compounds. the hydrogen atoms were placed in calculated positions with assigned isotropic thermal parameters. $U(\mathrm{H})=1.2 U_{\mathrm{eq}}(\mathrm{C})$. and allowed to ride on their parent atoms. Computations were carried out using the SHELXTL PC program system. ${ }^{18}$

Crystallographic data for the structures reported here have been deposited with CCDC (Deposition No.: CCDC-234644 for complex 1 and 234645 for complex 2). These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/

## Results and Discussion

## Description of the Structures.

Triaqua(4hydroxypyridine-2,6dicarboxylato-k ${ }^{3} \mathrm{~N}, \mathrm{O}, \mathrm{O}^{\prime}$ )M(II) acetonitrile-water( $\mathbf{1 / 0 . 2 5} / \mathbf{1})$ : The selected bond distances and angles for $\left[\mathrm{M}\left(\mathrm{C}_{7} \mathrm{H}_{2} \mathrm{NO}_{5}\right)\left(\mathrm{H}_{2} \mathrm{O}\right)_{3}\right] \cdot 0.25$ $\left(\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{~N}\right) \cdot\left(\mathrm{H}_{2} \mathrm{O}\right)(\mathrm{M}=\mathrm{Ni}(\mathrm{II}) 1, \mathrm{Co}(\mathrm{II}) 2)$ are listed in Table 2. The drawing of the molecular structure is shown in Figure 1.
The two compounds presented are isostructures with the same space group $C 2 / c$, and compound 1 is discussed in details. The coordination enviromment of the metal atoms in 1 and 2 is six-coordinated by one nitrogen and two oxygen atoms from the chelidamic acidligand and three water molecules to form a distorted octahedral conformation. as shown in Figure I. The center atoms and the Chelidanic acid ligand in $\mathbf{1}$ and $\mathbf{2}$ are coplanar with a mean deviation of $0.019(2) \AA$ and $0.024(2) \AA$, respectively. The three Ni O(water) bond distances are not equal, in which those with the coordinated water molecules occupying the axial positions of octahedron ( $\mathrm{Ni}-\mathrm{OlW}=2.087(4) \AA$ and $\mathrm{Ni}-\mathrm{O} 2 \mathrm{~W}$ $=2.083(4) \mathrm{A})$ are obviously longer than that with the coordinated water molecule locating on the equatorial plane ( $\mathrm{Ni}-\mathrm{O} 3 \mathrm{~W}=2.021(3) \AA$ ). The bond angles of nickel(II) ion

Figure 1. Molecular structure of $\mathbf{1}$ and 2 showing $30 \%$ displacement ellipsoids with H atoms being omitted for clatity.
and neighbor oxygen atoms from water are in the range of 85.4(2)-86.6(2), which are comparable with those of the previously reported zine analog ${ }^{17}$ and iron analog. ${ }^{16}$ In contrast, the bond angles of $\mathrm{Ni}-\mathrm{Ni}-\mathrm{O} 11$ and $\mathrm{N} 1-\mathrm{Ni}-\mathrm{O} 13$ are $78.6(1)$ and $76.7(1)^{\circ}$, because of the strain of the tridentate ligand. The CI3-O15 bond distance in $1(1.338(6) \AA)$ and 2 ( $1.351(3) \dot{A}$ ), which is close to $1.36 \AA$ characteristic of $\mathrm{C}-\mathrm{O}$ bonds in aromatic alcohols, ${ }^{17}$ indicates that the pyridine ring exhibits the enolic form upon coordination. ${ }^{20}$ The rest of the $\mathrm{N}-\mathrm{C}, \mathrm{C}-\mathrm{C}$ and C-O bond distances of the Chelidamic acid ligand are all agree well with those found in chelidamic acid."

The atoms 03 W and O 11 of the nickel complex act as hydrogen bond acceptors to form intermolecular hydrogen bonds with the atoms O 14 and O 15 from another one with the $\mathrm{O} 3 \mathrm{~W} \cdots \mathrm{O} 14$ distance of $2.868(6) \AA$ and the $\mathrm{O} 11 \cdots \mathrm{O} 15$ distance of $2,635(4) \AA$, respectively. As shown in Figure 2. the above two types of hydrogen bonds link the nickel complexes to form an infinite chain extending along the [ 11 $0]$ direction, which interlinks with its crystallographic inversion center-related chain through the $\mathrm{O} 2 \mathrm{~W} \cdots \mathrm{O} 12$ hydrogen bonds ( $2.834(5) \AA$ ) to form a double chain. The neighboring double chains are H -bonding bridged by lattice water molecules O4W (O1W O4W-2.844(6). O2W $\mathrm{O} 4 \mathrm{~W}=2.831(6) \AA)$ and interlinked through OlW O 12 hydrogen bonds ( $2.717(5) \AA$ ) to form a layer-like structure along the $\left[\begin{array}{lll}0 & 0\end{array}\right]$ direction. The layers are interlinked to each other through the $\mathrm{O} 4 \mathrm{~W} \cdots \mathrm{O} 14$ and $\mathrm{O} 3 \mathrm{~W} \cdots \mathrm{O} 13$ hydrogen bonds $(\mathrm{O} 4 \mathrm{~W} \cdots \mathrm{OI} 4=2.714(7), \mathrm{O} 3 \mathrm{~W} \cdots \mathrm{Ol} 3=2.695(5) \AA)$ to form a 3-D framework along the [ $\left.0 \begin{array}{lll}0 & 1 & 1\end{array}\right]$ direction, between

which the disordered acetonitrile molecules are located (the hydrogen bonds around the acetonitrile molecules are not discussed here), as shown in Figure 3.

Unlike the previously reported analogs of $\mathrm{V}, \mathrm{Cr}$ and Fe , it is worth noting that the bond lengths of $\mathrm{M}-\mathrm{O} 11$ in 1 and 2 are 0.075 (3) and 0.051 (2) $\AA$ longer than those of the $\mathrm{M}-\mathrm{O} 13$, respectively, which is probably due to the existence of a $\mathrm{O} 15 \cdots \mathrm{O} 11$ hydrogen bond. A similar case is also found in the 7 n analog. ${ }^{17}$

Chemical Properties: The TG analysis showed that the two complexes were steady as they lost little weight until about $100{ }^{\circ} \mathrm{C}$ (loss of about $2 \%$ ). The TG analysis of a pure sample of $1(6.581 \mathrm{mg})$ in nitrogen flow showed continuous steps of weight loss (from 37.1 to $263.2{ }^{\circ} \mathrm{C}$ ), which corresponded to the water and acetonitrile loss (exp. 25.06\%, calc. for $\left.\left(\mathrm{H}_{2} \mathrm{O}\right)_{3} \cdot 0.25\left(\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{~N}\right) \cdot\left(\mathrm{H}_{2} \mathrm{O}\right) 25.62 \%\right)$. Similar to 1 , the TG analysis of a pure sample of $2(5.255 \mathrm{mg})$ in nitrogen flow showed continuous steps of weight loss from 26.6 to $249.2^{\circ} \mathrm{C}$, which corresponded to the water and acetonitrile loss (exp. $24.99 \%$, calc. for $\left(\mathrm{H}_{2} \mathrm{O}\right)_{:} \cdot 0.25\left(\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{~N}\right) \cdot\left(\mathrm{H}_{2} \mathrm{O}\right)$ $25.64 \%$ ).

Variable-temperature magnetic susceptibility data were collected for the pure crystal sample of 2 . The temperaturedependent magnetic susceptibility measurement for 2 has confirmed that the cobalt ion is in a formal oxidation state of -2 by which the cobalt compound satisfied the neutrality requirement. A $1 / \chi_{\mathrm{M}}-T$ plot in Figure 4 shows that the phase is paramagnetic over $5-300 \mathrm{~K}$. For $2(\mathrm{Co})$, in the $70<\mathrm{T}<$ 300 K range, a non-linear fit wia $\chi_{1}=C /(T-\theta)+\chi_{0}$ reveals a Curie-Weiss behavior with the Curie constant ( ${ }^{\prime}=2.89(2)$ $\mathrm{cm}^{3} \mathrm{~mol}^{-1} \mathrm{~K}$. the Weiss constant $\theta--16.3(4) \mathrm{K}$, and the background susceptibility, $\chi_{11}=5.4 \times 10^{-4} \mathrm{~cm}^{3} / \mathrm{mol}$. The large negative Weiss constant indicates that it is possible for spin-orbit coupling and an antiferromagnetic interaction to exist, which assume to be transferred by the intermolecular hydrogen bonds and the dipole-dipole exchange interaction.

An effective magnetic moment of $4.81 \mu_{3}$ can thus be

Figure 4. Inverse molar susceptibility with temperature for $\mathbf{2}$. The gradual but significant decrease of $\mu_{\text {cff }}$ upon cooling suggests the presence of antiferromagnetic interactions.
obtained for each Co center, which lies within the range of typical experimental values (4,3-5.2 $\mu_{\mathrm{B}}$ ). ${ }^{21}$ It is obviously higher than the spin-only one $\left(\mu_{\mathrm{ef}}=3.87 \mu_{H_{3}}\right)^{21}$ suggesting that there is a small orbital angular moment contribution to the effective magnetic moment of the cobalt(il) ion. The antiferromagnetic interaction is reflected in the $\mu_{\mathrm{en}}-T$ plot of Figure 4 with the effective magnetic moment decreased upon cooling $\left(\mu_{\mathrm{eff}}=2.828^{*}\left(\chi_{\mathrm{M}_{1}} 7\right)^{12} \mu_{\mathrm{B},} \chi_{\mathrm{NI}_{1}}{ }^{\prime}=\chi_{\mathrm{M}}-\chi_{\mathrm{N}}\right)$. The significant decrease of $\mu_{\mathrm{eff}}$ for 2 at low temperatures is considered to be one result of the zero-field splitting of ground state. However, the origin for the small dip around 10 K for 2 (Co) in Figure 4 is still unclear.
As the crystal structure of 2 showing a distorted octahedral coordination geometry around the cobalt(11) ion. the $S=3 / 2$ state splits into two zero-field splitting states because of the axial distortion and the spin-orbit coupling interaction. The spin Hamiltonian $( \pm 1)$ takes on the form ( $D$ is 7FS parameter): $\mathrm{H}=g / \beta \mathrm{S} \cdot \overline{\mathrm{H}}+\mathrm{D}\left[\mathrm{S}_{\overline{7}}^{-}-\mathrm{S}(\mathrm{S}-1) / 3\right]$. from which the energy levels could be figured out. After the substituting of each energy level into the Van Vleck equation, the two following formulas of magnetisability are deduced (in the formulas, $x=D / \mathrm{Kl}^{\prime}$ ):

$$
\begin{aligned}
& \chi_{:}=\frac{\mathrm{Ng}^{2} \beta^{2}}{4 \mathrm{kT}} \frac{1+9 \exp (-2 x)}{1+\exp (2 x)} \\
& \chi_{\perp}=\frac{\mathrm{Ng}^{2} \beta^{2}}{4 \mathrm{k} T} \frac{1+3 / 4 x(1 \exp (2 x))}{1-\exp (-2 x)}
\end{aligned}
$$

From the formula $\chi_{\mathrm{m}}-\left(\chi_{;} \cdot 2 \chi-\right) / 3$, considering the intermolecular interaction and introducing the molecular field correction. ${ }^{11}$ the following equation applies: $\chi_{\mathrm{m}}{ }^{\prime}-\chi_{\mathrm{m}}$ / ( $1-2 \pi \mathrm{~J} \chi_{\mathrm{m}} / \mathrm{Ng}^{2} \beta^{2}$ ). Via this equation, an $\chi_{\mathrm{m}}-T$ plot in Figure 5 shows the fitting of variable-temperature magnetic susceptibility data with $\mathrm{D} / \mathrm{k}--6.31 \mathrm{~K}, \mathrm{~g}-2.73, \mathrm{~J} / \mathrm{k}--2.58$ $K$. The negative $z J$ value suggests that an antiferromagnetic interaction exists in 2 , which gives the same conclusion as the result of the fitting via the Curie-Weiss's Law.
