# ESTIMATION OF THE BIPLANAR CROSSING NUMBERS 

Ki Sung Park

#### Abstract

This paper is a sequel to our earlier research on biplanar drawings [4] and biplanar crossing numbers [3]. The biplanar crossing number $c r_{2}(G)$ of a graph $G$ is $\min \left\{c r\left(G_{1}\right)+\operatorname{cr}\left(G_{2}\right)\right\}$, where $c r$ is the planar crossing number and $G=G_{1} \cup G_{2}$. In this paper we show that $c r_{2}(G) \leq \frac{3}{8} \operatorname{cr}(G)$.

## 1. Introduction

Recall that a graph $G$ is biplanar, if one can write $G=G_{1} \cup G_{2}$, where $G_{1}$ and $G_{2}$ are planar graphs. Owen [2] introduced the biplanar crossing number of a graph $G$, that we denote by $\operatorname{cr}_{2}(G)$. One can define $\operatorname{cr}_{k}(G)=\min \left\{\operatorname{cr}\left(G_{1}\right)+\operatorname{cr}\left(G_{2}\right)+\cdots+\operatorname{cr}\left(G_{k}\right)\right\}$, similarly for any $k \geq 2$, making $G$ a union of $k$ subgraphs, but perhaps $k=2$ is more relevant for VLSI for the following reason: one always can realize $c r_{2}(G)$ by drawing the edges of $G_{1}$ and $G_{2}$ one two different sides of the same plane, while identical vertices of $G_{1}$ and $G_{2}$ are placed to identical locations on the plane.

This article deals with the problem of estimating on the biplanar crossing number.

## 2. Preliminaries

Let $\operatorname{cr}(G)$ denote the standard crossing number of the graph $G$, i.e. the minimum number of crossings of its edges over all possible drawings of $G$ in the plane, under the usual rules for drawings for crossing numbers [6]. For instance, a graph is planar if and only if its crossing number is zero.

Received January 31, 2005.
2000 Mathematics Subject Classification: 05C90.
Key words and phrases: crossing number, biplanar crossing number .

Definition. For the planar graphs $G_{1}$ and $G_{2}$, we denote the biplanar crossing number of a graph $G$ by $\mathrm{cr}_{2}(G)$. Here

$$
c r_{2}(G)=\min \left\{c r\left(G_{1}\right)+\operatorname{cr}\left(G_{2}\right)\right\},
$$

where the minimum is taken over all unions $G=G_{1} \cup G_{2}$.
A biplanar drawing of a graph $G$ means drawings of two subgraphs, $G_{1}$ and $G_{2}$, of $G$, on two disjoint planes under the usual rules for drawings for crossing numbers, such that $G=G_{1} \cup G_{2}$.

Definition. The thickness of the planar graphs $G$,

$$
\Theta(G)=\min \left\{k: G=G_{1} \cup \cdots \cup G_{k}\right\},
$$

where $G_{1}, \cdots, G_{k}$ are planar.
By definition, $c r_{2}(G)=0$ if and only if $\Theta(G) \leq 2$, i.e. $G$ is biplanar.
Euler's polyhedral formula states that $v-e+f=2$, where $v$ is the number of vertices, $e$ is the number of edges and $f$ is the number of faces. Any face is bounded by at least three edges and every edge touches at most two faces. Then $e-v+2=f \leq \frac{2}{3} e$ and $e \leq 3 v-6$ if $v \geq 3$, which is true for all planar graphs with $m$ edges and $n$ vertices.

For any graph $G$ with $m$ edges and $n$ vertices, we consider a diagram of $G$ which has exactly $\operatorname{cr}(G)$ crossings. Each of these crossings can be removed by removing an edge from $G$. Thus we can find a graph with at least $m-c r(G)$ edges and $n$ vertices with no crossings, and is thus a planar graph. From the above results follows $m-\operatorname{cr}(G) \leq 3 n-6$ and hence

$$
c r_{2}(G) \geq m-6 n+12
$$

## 3. The estimates of the biplanar crossing number

Theorem 3.1. Let $G$ be a graph with order $n$ and size $m$. For all $c>6$, if $m \geq c n$, then

$$
c r_{2}(G) \geq \frac{c-6}{c^{3}} \frac{m^{3}}{n^{2}} .
$$

Proof. Let $D$ be a nice drawing that realize $c r_{2}(G)$, take $p=\frac{c n}{m} \leq 1$, pick each vertex in $D$ with probability $p$, which will result in a random subdrawing $D^{\prime}$, then

$$
c r_{2}\left(D^{\prime}\right) \geq m\left(D^{\prime}\right)-6 n\left(D^{\prime}\right)+12
$$

take expectations, we have

$$
p^{4} c r_{2}(G) \geq m p^{2}-6 n p
$$

and hence

$$
c r_{2}(G) \geq \frac{m}{p^{2}}-\frac{6 n}{p^{3}}=\frac{m^{3}}{c^{2} n^{2}}-\frac{6 n m^{3}}{c^{3} n^{3}}=\frac{c-6}{c^{3}} \frac{m^{3}}{n^{2}} .
$$

Theorem 3.2. For all graph $G, c r_{2}(G) \leq \frac{3}{8} c r(G)$.
Proof. Without loss of generality we may assume that the input drawing is nice, i.e. any two edges of $G$ cross at most once, edges do not "touch", and edges sharing an endvertex do not cross; since all these assumptions do not change the crossing number.

Splitting Algorithm. INPUT any nice drawing $D$ of $G$ in the plane. Let $\operatorname{cr}(D)$ denote the number of crossings in this drawing. Consider a random bipartition $(U, W)$ of $V(G)$ : for every vertex, independently toss a fair coin, and if Head is obtained, add it to $U$, otherwise to $V$. Now any crossing in $D$ occurs in 6 possible forms, according to which classes the endpoints of the crossing edges belong to:
it is a crossings of $U U, U U$ edges with probability $\frac{1}{16}$
it is a crossings of $W W, W W$ edges with probability $\frac{1}{16}$
it is a crossings of $U W, U W$ edges with probability $\frac{1}{4}$
it is a crossings of $U U, W W$ edges with probability $\frac{1}{8}$
it is a crossings of $U U, U W$ edges with probability $\frac{1}{4}$
it is a crossings of $W W, U W$ edges with probability $\frac{1}{4}$
Draw in the first plane the subdrawings spanned by $U$ and spanned by $W$, draw in the second plane the subdrawing of edges connecting $U$ to $W$. In the second plane we have the $U W, U W$ type crossings,
in expectation $\frac{1}{4} \operatorname{cr}(D)$. In the first plane we have the $U U, U U$ and $W W, W W$ type crossings, and also the $U U, W W$ type crossings. However, we easily get rid of the latter type of crossing, by a translation of the $W$ point set and its induced edges to sufficiently far away. Therefore, the first plane has in expectation $\frac{1}{8} \operatorname{cr}(D)$ crossings.

Unfortunately, not any kind of converse of Theorem 3.2 can be true, as the following theorem shows:

Theorem 3.3. ([5]) There are graphs $G$ with crossing number $\operatorname{cr}(G)=\Theta\left(m^{2}\right)$ (i.e. as large as possible) and biplanar crossing number $c r_{2}(G)=\Theta\left(\frac{m^{3}}{n^{2}}\right)$ (i.e. as small as possible), for any $m=m(n)$, where $\frac{m}{n}$ exceeds a certain absolute constant.

Open Problem. What is the infimum $c^{*}$ of those constants $c$, for which $\operatorname{cr}_{2}(G) \leq c \cdot c r(G)$ holds for every graph $G$ ?

In [2], Owens came up with a conjectured $c r_{2}$-optimal drawing of the complete graph $K_{n}$ which has about $\frac{7}{24}$ of the crossings of a conjectured cr-optimal drawing of $K_{n}$. This might give some basis to conjecture that $c^{*} \leq \frac{7}{24}$.
