

LINDELÖFICATION OF FRAMES

MEE KYUNG KHANG

ABSTRACT. We introduce a concept of countably strong inclusions \triangleleft and that of \triangleleft - σ -ideals and prove that the subframe $S(\triangleleft)$ of the frame σIdL of σ -ideals is a Lindelöfication of a frame L . We also deal with conditions for which the converse holds. We show that any countably approximating regular $D(\aleph_1)$ frame has the smallest countably strong inclusion and any frame which has the smallest $D(\aleph_1)$ Lindelöfication is countably approximating regular $D(\aleph_1)$.

1. Introduction and preliminaries

This section is a collection of basic definitions and results on frames. For general notions and facts concerning frames, we refer to Johnstone[10].

1.1. Frames.

DEFINITION 1.1. ([3]) A *frame* is a complete lattice L in which binary meet distributes over arbitrary join, that is, $x \wedge \bigvee S = \bigvee \{x \wedge s \in S\}$ for any x in L and any subset S of L .

We will denote the bottom element of a frame L by 0 or 0_L and the top element by e or e_L .

- EXAMPLE 1.2. (1) Every complete chain is a frame.
(2) Every complete Boolean algebra is a frame.
(3) For a topological space X , the open set lattice $\Omega(X)$ of X under the inclusion is a frame.
(4) For a topological space X , the regular open set lattice $O_{reg}(X)$ is a complete Boolean algebra and hence it is a frame.

2000 Mathematics Subject Classification: Primary 06D22 ; Secondary, 54D35.

Key words and phrases: frame, Lindelöf frame, Lindelöfication, $D(\aleph_1)$ frame, countably strong inclusion, σ -ideal, countably approximating frame.

DEFINITION 1.3. A *frame homomorphism* is a map $h : L \rightarrow M$ between frames L and M Preserving all finitary meets and binary joins.

For any element a of a frame L , the map $a \wedge _ : L \rightarrow L$ preserves arbitrary joins; hence it has a right adjoint, which will be denoted by $a \rightarrow _ : L \rightarrow L$. In particular, $a \rightarrow 0$ exists for any a in L and we write $a \rightarrow 0 = a^*$, called the *pseudocomplement* of a .

PROPOSITION 1.4. *Let L be a frame and a, b in L . Then we have :*

- (1) $0^* = e$ and $e^* = 0$.
- (2) $a \wedge a^* = a^{**} \wedge a^* = 0$.
- (3) $a \leq a^{**}$.
- (4) *If $a \leq b$, then $a^* \geq b^*$.*
- (5) $(\bigvee_{i \in I} a_i)^* = \bigwedge_{i \in I} a_i^*$ for any family $(a_i)_{i \in I}$ in L .

A frame homomorphism $h : L \rightarrow M$ has the right adjoint which will be denoted by h^* and given by

$$h^*(y) = \bigvee \{x \in L \mid h(x) \leq (y)\} (y \in M).$$

Then h^* has the following properties :

- (1) h is 1-1 if and only $h^* \circ h = id_L$.
- (2) h is onto if and only if $h \circ h^* = id_M$.

DEFINITION 1.5. A frame homomorphism $h : L \rightarrow M$ is said to be :

- (1) *dense* if $h(a) = 0$ implies $a = 0$.
- (2) *codense* if $h(a) = e$ implies $a = e$.

1.2. Some Special Frames.

DEFINITION 1.6. ([8]) Let L be a frame and a, b in L . We say that a is *rather below* b , if there exists c in L such that $a \wedge c = 0$ and $b \vee c = e$, equivalently, $a^* \vee b = e$. In this case, we write $a \prec b$.

We note that $u \prec v$ in $\Omega(X)$ means $\bar{u} \subseteq v$, for a topological space $(X, \Omega(X))$.

PROPOSITION 1.7. *Let L be a frame and a, b, x, y in L . Then*

- (1) $0 \prec x$ and $x \prec e$.
- (2) $a \prec a$ if and only if a is complemented.
- (3) $a \prec b$ implies $a \leq b$.
- (4) *If $x \leq a \prec b \leq y$, then $x \prec y$.*

- (5) If $a \prec b$ and $x \prec y$, then $a \wedge x \prec b \wedge y$ and $a \vee x \prec b \vee y$.
 (6) $a \prec b$ implies $b^* \prec a^*$.

PROPOSITION 1.8. Let L and M be bounded distributive lattices and $f : L \rightarrow M$ a bounded lattice homomorphism. Then f preserves \prec .

DEFINITION 1.9. A frame L is said to be *regular* if for any a in L , $a = \bigvee \{b \in L \mid b \prec a\}$.

It is clear that a topological space $(X, \Omega(X))$ is regular if and only if $\Omega(X)$ is a regular frame.

DEFINITION 1.10. Let L be a complete lattice and a, b in L . We say that a is *way below* b and write $a \ll b$, if for any subset S of L , $b \leq \bigvee S$ implies $a \leq \bigvee E$ for some finite subset E of S .

EXAMPLE 1.11. Let $(X, \Omega(X))$ be a locally compact space. Then $u \ll v$ in $\Omega(X)$ if and only if there is a compact subset w of X such that $u \subseteq w \subseteq v$.

In [8], we have the following :

DEFINITION 1.12. A complete lattice L is said to be *continuous*, if for any a in L , $a = \bigvee \{x \in L \mid x \ll a\}$.

PROPOSITION 1.13. If L is a continuous frame, then the relation \ll interpolates, i.e., for $x \ll y$, there is z in L with $x \ll z \ll y$.

DEFINITION 1.14. Let L be a complete lattice and a, b in L . We say that a is *countably way below* b and write $a \ll_c b$, if for any subset S of L , $b \leq \bigvee S$ implies $a \leq \bigvee C$ for some countable subset C of S .

- EXAMPLE 1.15. (1) Let A and B be subsets of a set X . Then $A \ll_c B$ in the frame $\wp(X)$ of the power set of X if and only if there is a countable subset C of X with $A \subseteq C \subseteq B$.
 (2) In $\Omega(X)$ of a topological space $(X, \Omega(X))$, $u \ll_c v$ if there is a Lindelöf subset w of X with $u \subseteq w \subseteq v$. If X is locally Lindelöf, then the converse also holds.

PROPOSITION 1.16. Let L be a frame and a, b, x, y in L . Then

- (1) $0 \ll_c a$.
 (2) $a \ll_c b$ implies $a \leq b$.
 (3) If $x \leq a \ll_c b \leq y$, then $x \ll_c y$.
 (4) If $a_n \ll_c b$ for all $n \in N$, then $\bigvee_{n \in N} a_n \ll_c b$.

(5) If $a \ll b$, then $a \ll_c b$.

DEFINITION 1.17. ([11]) A complete lattice L is said to be *countably approximating*, if for any x in L , $x = \bigvee \{a \in L \mid a \ll_c x\}$.

EXAMPLE 1.18. (1) A continuous frame L is countably approximating by (5) of Proposition 1.16.

(2) If a frame is countable, then it is countably approximating.

(3) The frame $\Omega(X)$ of a locally Lindelöf space $(X, \Omega(X))$ is countably approximating.

2. Lindelöfication of a Frame

In this section, we deal with Lindelöfications of frames. We define countably strong inclusions on a frame and study relationship between Lindelöfications and countably strong inclusions.

2.1. Lindelöf Frames. The following definition is a natural generalization of compact frames.

DEFINITION 2.1. A frame L is said to be a *Lindelöf frame*, if for any subset S of L with $\bigvee S = e$, there is a countable subset C of S such that $\bigvee C = e$.

REMARK. (1) A topological space $(X, \Omega(X))$ is a Lindelöf space if and only if $\Omega(X)$ is a Lindelöf frame.

(2) A frame L is a Lindelöf frame if there is a countable subset B of L such that for any x in L , $x = \bigvee B'$ for some $B' \subseteq B$. Thus the regular open set lattice $O_{reg}(R)$ of the real line R is a non-spatial Lindelöf frame.

Using the definition of a closed sublocale and codense homomorphism, we obtain :

PROPOSITION 2.2. *A closed sublocale of a Lindelöf frame is a Lindelöf frame.*

PROPOSITION 2.3. *If $h : L \rightarrow M$ is a codense frame homomorphism and M is a Lindelöf frame, then L is a Lindelöf frame.*

A 1-1 frame homomorphism is clearly codense and therefore the following is immediate;

COROLLARY 2.4. *If $h : L \rightarrow M$ is a 1-1 frame homomorphism and M is a Lindelöf frame, then L is a Lindelöf frame.*

DEFINITION 2.5. A frame L is said to be a $D(\aleph_1)$ frame, if for any a in L and any sequence $(b_n)_{n \in N}$ in L , $a \vee (\bigwedge_{n \in N} b_n) = \bigwedge_{n \in N} (a \vee b_n)$.

- EXAMPLE 2.6.** (1) Suppose $\Omega(X)$ of a topological space X is closed under countable intersections, then $\Omega(X)$ is a $D(\aleph_1)$ frame. In particular, for any topological space X , the topology generated by the set of all G_δ -sets in the space is a $D(\aleph_1)$ frame.
- (2) Every completely distributive frame is $D(\aleph_1)$.
- (3) Every complete Boolean algebra is $D(\aleph_1)$ and hence atomless complete Boolean algebra is non-spatial $D(\aleph_1)$.
- (4) The regular open set lattice $O_{reg}(R)$ of the real line R is a non-spatial Lindelöf $D(\aleph_1)$ frame. But the open set frame $\Omega(R)$ of the real line is not $D(\aleph_1)$.

PROPOSITION 2.7. *If $x_n \prec y$ for all n in N in a $D(\aleph_1)$ frame L , then $\bigvee_{n \in N} x_n \prec y$ in L .*

Proof. By the assumption, $x_n^* \vee y = e$ for all n in N . Since L is $D(\aleph_1)$, $(\bigvee_{n \in N} x_n)^* \vee y = (\bigwedge_{n \in N} x_n^*) \vee y = \bigwedge_{n \in N} (x_n^* \vee y) = e$. Thus $\bigvee_{n \in N} x_n \prec y$. \square

2.2. Lindelöfication of a Frame. In this section, we introduce a concept of countably strong inclusions and using these, we construct Lindelöfication of frames.

DEFINITION 2.8. A binary relation \triangleleft on a frame L is said to be a *countably strong inclusion*, if it satisfies :

- (1) if $x \leq a \triangleleft b \leq y$, then $x \triangleleft y$.
- (2) \triangleleft is closed under finite meets and countable joins.
- (3) $a \triangleleft b$ implies $a \prec b$.
- (4) \triangleleft interpolates.
- (5) $a \triangleleft b$ implies $b^* \triangleleft a^*$.
- (6) $a = \bigvee \{x \in L \mid x \triangleleft a\}$ for any a in L .

REMARK. (1) A binary relation \triangleleft on a frame with the condition 1) in the above definition satisfies 2) if and only if \triangleleft satisfies :

- (i) $e \triangleleft e$; if $x \triangleleft y_1$ and $x \triangleleft y_2$, then $x \triangleleft y_1 \wedge y_2$ and
- (ii) if $x_n \triangleleft y$ for all n in N , then $\bigvee_{n \in N} x_n \triangleleft y$.

(2) Let X be a set. Then \subseteq is a countably strong inclusion on $\wp(X)$.

By proposition 1.7, we have the following :

PROPOSITION 2.9. *If L is a Lindelöf regular $D(\aleph_1)$ frame, then \prec is a countably strong inclusion.*

EXAMPLE 2.10. (1) $\wp(\mathbb{N})$ is a Lindelöf regular $D(\aleph_1)$ frame.

(2) Let X be an uncountable set and p a particular point of X . Define a topology on X by declaring open any set whose complement either is countable or includes p . Then $\Omega(X)$ is a Lindelöf regular $D(\aleph_1)$ frame.

We will investigate the relationship between countably strong inclusions and Lindelöfication.

DEFINITION 2.11. A *Lindelöfication* of a frame L is a dense, onto frame homomorphism $h : L \rightarrow M$ such that M is a Lindelöf regular frame.

Consider a dense onto frame homomorphism $h : L \rightarrow M$ with the right adjoint $h^* : L \rightarrow M$. We define a relation \triangleleft on L as follows : $x \triangleleft y$ if and only if $h^*(x) \prec h^*(y)$ for any x, y in L . Then since h is onto, $h \circ h^* = id_L$ and hence $\triangleleft \subseteq \overset{2}{h}(\prec)$, where $\overset{2}{h}$ denotes the map $h \times h$.

Using these notions, we have the following:

PROPOSITION 2.12. $\triangleleft = \overset{2}{h}(\prec)$

Proof. Suppose $u \prec v$ in M and let $h(u) = x$ and $h(v) = y$. Then $v \leq h^*(y)$; hence $u \prec h^*(y)$. Thus there exists t in M such that $u \wedge t = 0$ and $h^*(y) \vee t = e$. Since h is onto, $h(h^*(x) \wedge t) = h(h^*(x)) \wedge h(t) = x \wedge h(t) = h(u) \wedge h(t) = h(u \wedge t) = 0$. Since h is dense, $h^*(x) \wedge t = 0$. Thus $h^*(x) \prec h^*(y)$; hence $x \triangleleft y$. \square

The properties of pseudocomplements and dense homomorphisms lead us the following :

LEMMA 2.13. *For a dense onto homomorphism $h : M \rightarrow L$, $(h^*(a))^* = h^*(a)^*$ for all a in L .*

PROPOSITION 2.14. *Suppose that $h : M \rightarrow L$ is a Lindelöfication of a frame L and M is a $D(\aleph_1)$ frame. Then the relation \triangleleft defined as above is a countably strong inclusion on L .*

In the following, we construct a Lindelöfication from a countably strong inclusion. For this, we study some properties of σ -ideals.

We recall that a subset D of a poset L is said to be *countably directed*, if every countable subset of D has an upper bound in L .

DEFINITION 2.15. A subset I of a frame L is said to be a σ -ideal if it is a countably directed lower set, equivalently, it is a lower set and closed under countable joins.

Let σIdL denote the set of all σ -ideals in L . Then σIdL is clearly closed under arbitrary intersections in the power set lattice $\wp(L)$ of L and therefore it is a complete lattice.

- EXAMPLE 2.16. (1) Let X be an infinite set. $\text{Count}(X) = \{S \subseteq X \mid S \text{ is a countable set}\}$ is a σ -ideal of $\wp(X)$. $\text{Fin}(X) = \{F \subseteq X \mid F \text{ is a finite set}\}$ is an ideal but not a σ -ideal of $\wp X$.
- (2) If L is a $D(\aleph_1)$ frame, then for any a in L , $\{x \in L \mid x \prec a\}$ is a σ -ideal of L by Proposition (2.7).
- (3) For a frame L and a in L , $\downarrow_c a = \{x \in L \mid x \ll_c a\}$ is a σ -ideal of L by (1), (3) and (4) in Proposition (1.16).

LEMMA 2.17. For $(I_\lambda)_{\lambda \in \Lambda} \subseteq \sigma IdL$, $\bigvee_{\lambda \in \Lambda} I_\lambda = \{ \bigvee_{k \in \mathbb{N}} x_k \mid (x_k)_{k \in \mathbb{N}} \text{ is a sequence in } \bigcup_{\lambda \in \Lambda} I_\lambda \}$ in σIdL .

PROPOSITION 2.18. σIdL is a Lindelöf frame.

We now consider the set of all \triangleleft - σ -ideal in a frame L as a candidate of a Lindelöfication of L .

DEFINITION 2.19. Let I be a σ -ideal and \triangleleft a countably strong inclusion on L . Then I is said to be a \triangleleft - σ -ideal if for any a in I , there is b in I such that $a \triangleleft b$.

PROPOSITION 2.20. Let \triangleleft be a countably strong inclusion on a frame L . Then for any a in L , $\{x \in L \mid x \triangleleft a\}$ is a \triangleleft - σ -ideal.

We note that for a Lindelöf regular $D(\aleph_1)$ frame L , \prec is a countably strong inclusion on L and hence for any a in L , $\{x \in L \mid x \prec a\}$ is a \prec - σ -ideal.

In the following, let \triangleleft denote a countably strong inclusion on a frame L and let $S(\triangleleft)$ denote the set of all \triangleleft - σ -ideals in L .

PROPOSITION 2.21. $S(\triangleleft)$ is a Lindelöf subframe of σIdL .

Consider $j : \sigma IdL \rightarrow L$ defined by $j(J) = \bigvee J$ and the restriction $j_0 : S(\triangleleft) \rightarrow L$ of j . Since j is a dense homomorphism, so is j_0 .

Consider $k : L \rightarrow S(\triangleleft)$ defined by $k(a) = \{x \in L \mid x \triangleleft a\}$. Then k is well defined by Proposition (2.20), and $\bigvee k(a) = a$, for \triangleleft is a countably strong inclusion. Thus $j_0(k(a)) = a$ for all $a \in L$. So j_0 is onto.

The following is immediate from the definition of \triangleleft - σ -ideals.

LEMMA 2.22. For any J in $S(\triangleleft)$, $J = \bigcup_{a \in J} k(a)$.

LEMMA 2.23. If $x \triangleleft a$, then $k(x) \prec k(a)$.

PROPOSITION 2.24. $S(\triangleleft)$ is regular.

Proof. For any J in $S(\triangleleft)$, $J = \bigcup_{a \in J} k(a)$ and for any a in J , there is x in J such that $a \triangleleft x$. By the above lemma, $k(a) \prec k(x) \leq J$. Thus $J = \bigcup_{a \in J} k(a) \leq \bigvee \{I \in S(\triangleleft) \mid I \prec J\} \leq J$; hence $J = \bigvee \{I \in S(\triangleleft) \mid I \prec J\}$. Therefore $S(\triangleleft)$ is regular. \square

Collecting the above results, we have the following :

THEOREM 2.25. Suppose \triangleleft is a countably strong inclusion on a frame L . Then $j_0 : S(\triangleleft) \rightarrow L$ is a Lindelöfication of L .

PROPOSITION 2.26. If L is $D(\aleph_1)$, then so is σIdL .

By Proposition 2.21, 2.24 and 2.26, we have the following :

COROLLARY 2.27. Suppose L is $D(\aleph_1)$ and \triangleleft is closed under countable meets. Then $S(\triangleleft)$ is $D(\aleph_1)$ and hence $j_0 : S(\triangleleft) \rightarrow L$ is a $D(\aleph_1)$ Lindelöfication of L .

We note that if L is $D(\aleph_1)$, then \prec is closed under countable meets. Indeed, $x \prec y_n$ for all $n \in N$ in L , then $x^* \vee (\bigwedge_{n \in N} y_n) = \bigwedge_{n \in N} (x^* \vee y_n) = e$ and therefore, $x \prec \bigwedge_{n \in N} y_n$.

NOTATION 2.28. In the following, $j_0 : S(\triangleleft) \rightarrow L$ will be denoted by $\mathcal{I}_L : S(\triangleleft) \rightarrow L$.

Let $\text{CS}(\mathbb{L})$ be the set of all countably strong inclusions on a frame \mathbb{L} . Then $(\text{CS}(\mathbb{L}), \subseteq)$ is a poset.

DEFINITION 2.29. Let $f : M \rightarrow \mathbb{L}$ and $g : N \rightarrow \mathbb{L}$ be Lindelöfications of a frame \mathbb{L} . If there is a frame homomorphism $h : M \rightarrow N$ with $g \circ h = f$, then we say that f is *smaller than* g and write $f \leq g$.

Note that if h exists in the above definition, it is unique since g is dense and hence a monomorphism for N is a regular frame. Moreover, if the reverse also holds, then h is an isomorphism, which shows that the equivalence relation associated with this preorder is just an isomorphism of Lindelöfications.

Let $\text{Lind}(\mathbb{L})$ be the set of all equivalent classes of Lindelöfications of \mathbb{L} . Then $(\text{Lind}(\mathbb{L}), \leq)$ is a poset. Consider maps $\varphi : \text{Lind}^*(\mathbb{L}) \rightarrow \text{CS}(\mathbb{L})$ defined by $\varphi(h : M \rightarrow \mathbb{L}) = \overset{2}{h}(\prec_M)$ and $\psi : \text{CS}(\mathbb{L}) \rightarrow \text{Lind}(\mathbb{L})$ defined by $\psi(\triangleleft) = (\mathcal{I}_{\mathbb{L}} : S(\triangleleft) \rightarrow \mathbb{L})$, where $\text{Lind}^*(\mathbb{L})$ denotes the set of all $D(\aleph_1)$ Lindelöfications of \mathbb{L} .

PROPOSITION 2.30. *The map φ and ψ are isotones.*

THEOREM 2.31. *Suppose \triangleleft is a countably strong inclusion on a frame \mathbb{L} such that $S(\triangleleft)$ is $D(\aleph_1)$. Then $\varphi(\psi(\triangleleft)) = \triangleleft$.*

Proof. Take any countably strong inclusion \triangleleft on \mathbb{L} and let $\triangleleft_0 = \varphi(\psi(\triangleleft))$ the countably strong inclusion determined by $\psi(\triangleleft)$. Note that $\bigvee J \leq a$ if and only if $J \subseteq k(a) = \{x \in \mathbb{L} \mid x \triangleleft a\}$ for all J in $S(\triangleleft)$ and a in \mathbb{L} because J is a \triangleleft - σ -ideal. Thus k is the right adjoint of $\mathcal{I}_{\mathbb{L}}$, the join map. Thus $x \triangleleft_0 y$ if and only if $k(x) = \mathcal{I}_{\mathbb{L}}^*(x) \prec \mathcal{I}_{\mathbb{L}}^*(y) = k(y)$ by Proposition 2.12. Suppose $x \triangleleft_0 y$, then there is J in $S(\triangleleft)$ such that $k(x) \wedge J = \{0\}$ and $k(x) \vee J = \mathbb{L}$. Thus we have $x \wedge \bigvee J = 0$, and $z \vee t = e$ for some $z \in k(y)$ and $t \in J$; hence $x \wedge t \leq x \wedge \bigvee J = 0$. Since z is in $k(y)$, $z \triangleleft y$. Thus $x \prec z \triangleleft y$; hence $x \triangleleft y$. Therefore $\triangleleft_0 \subseteq \triangleleft$. If $x \triangleleft y$, then $k(x) \prec k(y)$ i.e., $x \triangleleft_0 y$. Hence $\triangleleft \subseteq \triangleleft_0$. In all, $\triangleleft_0 = \triangleleft$. \square

LEMMA 2.32. *Let \mathbb{L} be a regular frame. Then any codense homomorphism $h : \mathbb{L} \rightarrow M$ is 1-1.*

LEMMA 2.33. *Let \mathbb{L} be a regular $D(\aleph_1)$ frame and M a Lindelöf frame. Then any dense homomorphism $h : \mathbb{L} \rightarrow M$ is codense.*

For a frame homomorphism $h : \mathbb{L} \rightarrow M$, let $\sigma \text{Id}h : \sigma \text{Id}\mathbb{L} \rightarrow \sigma \text{Id}M$ be the frame homomorphism assigning each σ -ideal J in \mathbb{L} , to the σ -ideal

$\downarrow h(J) = \bigcup_{a \in J} \{\downarrow h(a) \mid a \in J\}$. Then $\sigma \text{Id}h$ is a frame homomorphism. Thus σId is a functor from $\underline{\text{Frm}}$ to $\underline{\text{Frm}}$.

LEMMA 2.34. *Let M be a regular $D(\aleph_1)$ frame. Then $s : M \rightarrow \sigma \text{Id}M$ defined by $s(a) = \{x \in M \mid x \prec a\}$ is a frame homomorphism.*

THEOREM 2.35. *For a $D(\aleph_1)$ Lindelöfication $h : M \rightarrow L$ of a frame L , $\psi \circ \varphi(h) \cong M$.*

Proof. Let $\varphi(h) = \triangleleft$, then $x \triangleleft y$ if and only if $h^*(x) \prec h^*(y)$. It is enough to show that there is an isomorphism $f : M \rightarrow S(\triangleleft)$ such that $\mathcal{I}_L \circ f = h$.

Define $f : M \rightarrow S(\triangleleft)$ by $f(a) = \downarrow h\{x \in M \mid x \prec a\}$, which is clearly a σ -ideal in L . Since M is a Lindelöf regular $D(\aleph_1)$ frame, $x \prec a$ implies that $x \prec y \prec a$, for some y in M and hence $h(x) \triangleleft h(y)$ and $h(y)$ is in $f(a)$. Thus for any z in $f(a)$, $z \leq h(x)$ for some $x \prec a$; hence $z \triangleleft h(y)$ for some $h(y)$ in $f(a)$. Therefore $f(a)$ is in $S(\triangleleft)$. Thus f is well-defined. For any a in M , $\bigvee f(a) = \bigvee \{h(x) \mid x \prec a\} = h(a)$. Hence we have $\mathcal{I}_L \circ f = h$.

As noted above $f = (\sigma \text{Id}h) \circ s$, where $s(a) = \{x \in M \mid x \prec a\}$. Thus by lemma 2.34, f is a frame homomorphism.

Since h is dense, so is f ; hence f is 1-1 by the above lemma.

For any J in $S(\triangleleft)$, let $a = \bigvee h^{-1}(J)$. Assume that $x \prec a$ then $e = x^* \vee a = x^* \vee \bigvee h^{-1}(J)$ and therefore $e = x^* \vee \bigvee E$, for some countable subset E of $h^{-1}(J)$. Hence $x = x \wedge e = x \wedge (x^* \vee \bigvee E) = x \wedge \bigvee E$, so that $x \leq \bigvee E \in h^{-1}(J)$. Therefore $h(x)$ is in J . And if $h(x)$ is in J , then there is $h(y)$ in J such that $h(x) \triangleleft h(y)$, because h is onto. Thus $x \leq h^*h(x) \prec h^*h(y)$ and $h^*h(y) = \bigvee \{z \in M \mid h(z) \leq h(y)\} \leq a$. Hence $x \prec a$. This show that $h(x) \in J$ if and only if $x \prec a$. Since h is onto, $f(a) = \downarrow (h\{x \in M \mid x \prec a\}) = h(\{x \in M \mid x \prec a\})$, so that $f(a) = J$. In all, f is an isomorphism. This completes the proof. \square

2.3. The Smallest Lindelöfication. In this section, we deal with Lindelöfications of countably approximating frames.

PROPOSITION 2.36. *Let L be a countably approximating regular $D(\aleph_1)$ frames, then $x \ll_c y$ if and only if $x \prec y$ and $\uparrow x^*$ is a Lindelöf frame.*

Proof. (\Rightarrow) Suppose $x \ll_c y$. Since L is regular, $y = \bigvee \{z \in L \mid z \prec y\}$. Since L is $D(\aleph_1)$, $\{z \in y \mid z \prec y\}$ is countably directed and hence there is z in L such that $x \prec z$ and $x \leq z$, which implies $x \prec y$.

Since L is countably approximating, there exists z in L such that $x \ll_c z \ll_c y$. Take any $S \subseteq \uparrow x^*$ with $e = \bigvee S$. Then $y \leq e = \bigvee S$. Since $z \ll_c y$, there is $(a_n)_{n \in N}$ in S such that $z \leq \bigvee_{n \in N} a_n$. And $x \ll_c z$ implies $x \prec z$; hence $x \prec \bigvee_{n \in N} a_n$. Thus $e = x^* \vee (\bigvee_{n \in N} a_n) = \bigvee_{n \in N} (x^* \vee a_n) = \bigvee_{n \in N} a_n$. Hence $\uparrow x^*$ is a Lindelöf frame.

(\Leftarrow) Suppose that $y \leq \bigvee S$ for a subest S of L . Since $x \prec y$, $e = x^* \vee y = x^* \vee (\bigvee S) = \bigvee_{s \in S} (x^* \vee s)$. Since $\uparrow x^*$ is a Lindelöf frame, there is $(a_n)_{n \in N}$ in S such that $e = \bigvee_{n \in N} (x^* \vee s_n) = x^* \vee (\bigvee_{n \in N} s_n)$. Hence $x = x \wedge e = x \wedge (x^* \vee (\bigvee_{n \in N} s_n)) = x \wedge (\bigvee_{n \in N} s_n)$, which implies that $x \leq \bigvee_{n \in N} s_n$. Therefore $x \ll_c y$. \square

REMARK. In any frame L , if $x \prec y$ and $\uparrow x^*$ is a Lindelöf frame, then $x \ll_c y$. Furthermore, the relation \prec on any Lindelöf frame L implies \ll_c for $\uparrow x^*$ for any $x \in X$. Thus every Lindelöf regular frame is countably approximating, because $x = \bigvee \{y \in L \mid y \prec x\} \leq \bigvee \{y \in L \mid y \ll_c x\} \leq x$ for any x in L .

But the converse does not hold since the frame of the discrete topology on the real line is countably approximating but not a Lindelöf frame.

Using the above remark, we have the following corollary.

COROLLARY 2.37. *Let L be a Lindelöf regular $D(\aleph_1)$ frame and x, y in L . Then $x \ll_c y$ if and only if $x \prec y$.*

We define $a \triangleleft \triangleleft b$ in a frame L if and only if $a \prec b$, and $\uparrow a^$ or $\uparrow b$ is a Lindelöf frame.*

PROPOSITION 2.38. *Let L be a frame and a, b, x, y in L . Then*

- (1) *If $x \leq a \triangleleft \triangleleft b \leq y$, then $x \triangleleft \triangleleft y$.*
- (2) *If $x \triangleleft \triangleleft a$ and $x \triangleleft \triangleleft b$, then $x \triangleleft \triangleleft a \wedge b$.*
- (3) *If $x \triangleleft \triangleleft a$, then $a^* \triangleleft \triangleleft x^*$.*
- (4) *Suppose L is a $D(\aleph_1)$ frame, and $x_n \triangleleft \triangleleft a$ for all $n \in N$, then $\bigvee_{n \in N} x_n \triangleleft \triangleleft a$.*

PROPOSITION 2.39. *Suppose L is a countably approximating regular $D(\aleph_1)$ frame. Then $\triangleleft \triangleleft$ interpolates.*

Proof. Suppose that $x \triangleleft \triangleleft a$. Then $x \prec a$.

Assume that $\uparrow x^*$ is a Lindelöf frame. Then $x \ll_c a$ by Proposition 2.36, and since L is countably approximating, there is b in L such that $x \ll_c b \ll_c a$ and hence $x \prec b \prec a$. Since $x \prec b$ and $\uparrow x^*$ is a Lindelöf frame, $x \triangleleft \triangleleft b$. Since $b \ll_c a$ and $\uparrow b^*$ is a Lindelöf frame, $b \triangleleft \triangleleft a$. In all, $x \triangleleft \triangleleft b \triangleleft \triangleleft a$.

Assume that $\uparrow a$ is a Lindelöf frame. Since $x \prec a$, there is z in L such that $x \wedge z = 0$ and $a \vee z = e$. Thus $e = a \vee z = a \vee \bigvee \{u \in L \mid u \ll_c z\}$. Since $\uparrow a$ is a Lindelöf frame, there is a sequence $(u_n)_{n \in \mathbb{N}}$ in L such that $u_n \ll_c z$ and $a \vee \bigvee_{n \in \mathbb{N}} u_n = e$. Let $u = \bigvee_{n \in \mathbb{N}} u_n$. Then $u \ll_c z$ and hence $u \prec z$ and $z^* \prec u^*$. Since $x \leq z^*$, $x \prec u^*$. Since $u \ll_c z$, $\uparrow u^*$ is a Lindelöf frame and hence $x \triangleleft \triangleleft u^*$. Since $a \vee z = e$, $u^* \prec a$ and hence $u^* \triangleleft \triangleleft a$. In all, $x \triangleleft \triangleleft u^* \triangleleft \triangleleft a$. \square

Collecting the above propositions, we can conclude the following:

PROPOSITION 2.40. *If L is a countably approximating regular $D(\aleph_1)$ frame, then the relation $\triangleleft \triangleleft$ is a countably strong inclusion.*

THEOREM 2.41. *A countably approximating regular $D(\aleph_1)$ frame L has a smallest countably strong inclusion.*

Proof. By the above proposition, it is enough to show that a countably strong inclusion \triangleleft on L contains $\triangleleft \triangleleft$.

Suppose that $x \triangleleft \triangleleft y$. Then $x \prec y$.

Assume that $\uparrow x^*$ is a Lindelöf frame, then by Proposition 2.36, $x \ll_c y = \bigvee \{z \in L \mid z \triangleleft y\}$ and $\{z \in L \mid z \triangleleft y\}$ is countably directed. Thus there is z in L such that $x \leq z$ and $z \triangleleft y$ and hence $x \triangleleft y$.

Suppose that $\uparrow y$ is a Lindelöf frame. Since $x \prec y$, there is u in L such that $x \wedge u = 0$ and $y \vee u = e$. Thus $e = y \vee u = y \vee \bigvee \{v \in L \mid v \triangleleft u\}$. Since $\uparrow y$ is a Lindelöf frame, there is a sequence $(v_n)_{n \in \mathbb{N}}$ in L such that $y \vee (\bigvee_{n \in \mathbb{N}} v_n) = e$ and $v_n \triangleleft u$ for all $n \in \mathbb{N}$. Let $v = \bigvee_{n \in \mathbb{N}} v_n$. Then $v \triangleleft u$ and $y \vee v = e$. Thus $x \leq u^* \triangleleft v^* \leq y$; hence $x \triangleleft y$. This completes the proof. \square

We will show that a frame which has the smallest $D(\aleph_1)$ Lindelöfication is countably approximating regular.

LEMMA 2.42. *Let M be a Lindelöf regular $D(\aleph_1)$ frame and a an element of M . Then $M_a = \{x \in M \mid x \leq a \text{ or } x \vee a = e\}$ is a regular subframe of M .*

LEMMA 2.43. *Let M be a countably approximating frame and a in M . Then $\downarrow a$ is countably approximating.*

THEOREM 2.44. *Suppose that a frame L has the smallest Lindelöfication $h : M \rightarrow L$ such that M is $D(\aleph_1)$. Then L is a countably approximating regular frame.*

Proof. Case 1. L is a Lindelöf frame.

By Lemma 2.32 and 2.33, h is 1-1 and hence an isomorphism. Thus L is countably approximating regular because M is by above remark.

Case 2. L is not a Lindelöf frame.

Then h is not an isomorphism and hence not codense by Lemma 2.32. Thus there is a in M with $a < e$ and $h(a) = e$. Then M_a is a regular subframe of M where $M_a = \{x \in M \mid x \leq a \text{ or } x \vee a = e\}$, by Lemma 2.42.

Consider $\bar{h} : M_a \rightarrow L$ defined by $\bar{h}(x) = h(x)$, which is a frame homomorphism since M_a is a subframe of M . Since h is onto and $h(a) = e$, \bar{h} is also onto. Since M is a Lindelöf frame, so is M_a by Corollary 2.4. Moreover \bar{h} is dense for h is dense. Thus \bar{h} is a Lindelöfication of L . Since M_a is also closed under countable meets in M , M_a is also $D(\aleph_1)$. Since M is the smallest $D(\aleph_1)$ Lindelöfication, $M_a = M$ and hence for any x in M , $x \leq a$ or $x \vee a = e$.

Consider $\tilde{h} : \downarrow a \rightarrow L$ defined by $\tilde{h}(x) = h(x)$ which is an onto frame homomorphism by the same argument for \bar{h} .

If $b \leq a$ and $h(b) = e$, then $M_b = M = M_a$; hence $a \leq b$ or $b \vee a = e$. Since $b \leq a$ implies $a \vee b = a$, and $a < e$, $a \vee b \neq e$. Thus $a = b$. Therefore \tilde{h} is codense and 1-1 by Lemma 2.32 so that \tilde{h} is an isomorphism.

Since M_a is a Lindelöf regular frame and a is in M_a , $\downarrow a$ is countably approximating. Hence L is countably approximating for \tilde{h} is an isomorphism. This completes the proof. \square

REMARK. In the above proof, a is, in fact, a maximal element in M . Indeed, suppose that $a \leq b < e$. Then since $b \in M = M_a$, $b \leq a$ or $b \vee a = e$. But $b \vee a \neq e$, because $a \vee b = b < e$. Thus $a = b$.
