# Anti-Selective Dihydroxylation Reactions of Monosubstituted and ( $E$ )-Ester Conjugated Allylic Amines by Bulky Alkyl Groups 

Jongho Jeon, So-Hee Kim, Jong Hyup Lee, Joon Seok Oh, Doh Yeon Park, and Young Gyu Kim*<br>Department of Chemical and Biological Engineering. Seoul National Chiversin, Seoul 151-74. Korea<br>${ }^{\text { E-mail: yghimas.anu.ac. } \mathrm{kr}}$<br>Recenved January 31, 2009, Accepted March 11, 2009

#### Abstract

The $\mathrm{OsO}_{4}$-catalyzed dihydroxylations of a monosubstituted allylic amine and $\gamma$-amino- $\alpha, \beta$-unsaturated $(E)$-esters with bulky alkyl groups showed a high anti-selectivity. Since the acyclic conformation of F -acyloxy protected allylic amines was efficiently controlled by a bulky $t$ - Bu or OBO ester group, the anti diastereoselectivity of $>12.5: 1$ was obtained without applying a chiral reagent. The synthetic utility of the present method was demonstrated by a stereoselective and efficient synthesis of an $\alpha$-glucosidase inhibitor $\mathbf{1 5}$ from commercially available $\hat{N}$-Cbz-L-serine 6 in 11 steps and $31 \%$ yield.

Key Words: Asymmetric synthesis. Amino alcohols. Dilydroxylations. OBO ester

## Introduction

A dihydroxylation reaction of chiral ally lic amines with $\mathrm{OsO}_{4}$ is one of the convenient methods to produce an amino alcohol moiety that is a key motif present in numerous bioactive natural products and synthetic compounds. ${ }^{1}$ In the case of cyclic allylic amines. the desired facial selectivity of the dilydroxylation reactions could be effectively produced by substrate-or chelation-controlled reactions. ${ }^{-}$However the acyclic allylic amines with widely used $N$-acyl or $N$-acy losy protecting groups resulted in low or often inconsistent selectivity due to their flexible acyclic conformation. ${ }^{3}$ The wellestablished Sharpless asymmetric dilyy droxylation gave mixed results in several cases. ${ }^{4}$

We have been interested in the diastereoselective dilydroxylation reactions of acyclic allylic amines by controlling acyclic conformation of the substrates. Enhanced stereochemical results have been achieved by using the N-diarylmethylene ${ }^{5}$ or $\mathrm{N}, \mathrm{V}$-diBoc group ${ }^{6}$ instead of the N -acylony protecting groups. Since these protecting groups efficiently controlled the acyclic conformation of the allylic amines. the high diastereoselectivity was obtained without the need of chiral reagents. In a few cases. the stereoselectivities obtained from the above methods were better than those of the Sharpless asy mmetric dilyydroxylation.

However the above methods have a disadvantage that the readily available and versatile $A$-protecting groups such as an N -Boc or N -Cbz group cannot be used. Here. we would like to report that a bulky alkyl group of chiral allylic amines can be utilized to control effectively their acyclic conformation and a high and useful selectivity could be achieved even with the versatile and widely used $A-$ Boc or $N-\mathrm{Cbz}$ group.

In our previous report. the $\mathrm{OsO}_{4}$-catalyzed dihy droxylations of $\gamma$-amino- $\alpha, \beta$-unsaturated $(E)$-esters with the $\lambda$-diarylmethylene group gave consistent anti-selectivity (6.7:1 -

19:1). ${ }^{\text {sb }}$ The selectivities increased as the alkyl group of the substrates became larger. The similar stereochemical trend was observed by Reetz and coworkers with the N-Boc derivatives of the $\gamma$-amino- $\alpha, \beta$-unsaturated ( $E$ )-esters. ${ }^{3 \mathrm{c}}$ They reported the highest anti-selectivity of $c a .4 .3: 1$ when the alkyl group was an i-Pr group. The increased anti-selectivities (3.7:17:1) were also observed with the $V$-diarylmethylene derivatives of the monosubstituted ally lic amines. ${ }^{\text {sa }}$ Thus. we envisioned that a bulkier alkyl group such as a tert-alkyl group in both $\gamma$ -amino- $\alpha, \beta$-unsaturated ( $E$ )-esters and monosubstituted allylic amines would induce higher anti-selectivity even with the popular $h$-protecting groups and without any chiral reagents.

## Results and Discussion

First. we have examined the $\mathrm{OsO}_{4}$-catalyzed dilydroxylation of the $\hat{K}$-Boc derivatives of a monosubstituted allylic amine and $\gamma$-amino $\alpha . \beta$-unsaturated esters that have a tert-Bu group in the alkyl chain (Table 1). The starting compounds 1a-c were prepared from the Wittig olefination of the corresponding amino aldehyde that was derived from an oxidation of commercially available N -Boc-tert-leucinol. The dihydroxylations were conducted with catalytic amount of $\mathrm{OsO}_{4}$

Table 1. Dihydroxylations of allylic amines with a $t$-Bu group

Scheme 1. Assignment of the relative stereochemistry of $\mathbf{2 a}$.
and more than 2 equivalents of NMO as a co-oxidant and then the crude diol products were acetylated to give diacetates 2a-c. To our excitement. the dilydroxylation reaction of the $\gamma$ -amino- $\alpha, \beta$-unsaturated ( $E$ )-ester la showed a ratio of more than 20 to 1 for its anti-isomer on its ${ }^{1} \mathrm{H}$ NMR spectrum. The monosubstituted olefin 1c also resulted in the high antiselectivity. These stereoselective results with a bulky tert-butyl group were quite high compared with those of previously reported results. ${ }^{5 a}$ Especially, the substrate-controlled or chiral agent-controlled dihydroxylations of monosubstituted allylic amines exhibited low and (or) mixed selectivity with a few exceptions. ${ }^{3,7}$ On the other hand. the same reaction of $\gamma$ -amino- $\alpha . \beta$-unsaturated ( $Z$ )-ester 1b gave a 1:I diastereomeric mixture.

The relative stereochemistry of a mixture of the diol products from 1a was determined by transformation of the amino diol 3 into the corresponding $\gamma$-lactam derivatives 5 (Scheme 1). The N-Boc group of $\mathbf{3}$ was replaced with the N -Cbz group of 4 in two steps. Then. the N -Cbz protected diol 4 was treated under catalytic hydrogenation conditions to form a lactam ring after removal of the $\mathrm{N}-\mathrm{Cbz}$ group, which was followed by acetylation to give a diastereomeric misture of $\gamma$-lactams 5 . The coupling constant $J_{4,}$, of a major isomer of 5. 5 trans, was 6.1 Hz . whereas that of a minor isomer. 5 cis. showed larger value. 7.9 Hz . In general. the $J_{4.5}$ values of $c i s-\gamma-$ lactams are known to be larger than those of trans- $\gamma$ lactams. ${ }^{\text {ins }}$ Therefore the relative stereochemistry of the two hydroxyl groups in the major isomer of 2 a should be anti to the amino group. The anti-selectivity for the diacetates 2 c was also confirmed by measuring the $J_{4,5}$ value ( 7.3 Hz ) of the corresponding oxazolidinone compound derived from the major isomer of $\mathbf{2 c} .^{9}$ Another evidence for the configurational assignment is given below.

The ligh anti-selectivity exhibited by conjugated ( $E$ )-ester 1a and the monosubstituted olefin ic can be rationalized by employing the transition state models proposed by Houk. Kishi and Vedejs (Figure 1). ${ }^{10}$ According to the Houk model. a deactivating substituent such as the $N$-Boc group would take preferentially the 'inside' conformation $\mathbf{A}$ to minimize its orbital overlap with the $\mathrm{C}-\mathrm{C}$ double bond when the severe $\mathrm{A}^{1,3}$ ally lic strain is absent. Addition of $\mathrm{OSO}_{4}$ from the bottom side of the 'V-inside' conformer would give an anti diol as a major product. When the size of the alkyl group R is small, the ' N -outside' conformer $\mathbf{B}$ would compete with the ' N -inside ${ }^{*}$ conformer of $\mathbf{A}$, resulting in a reduced anti-selectivity. How-

ever. when R is a bulky $t$-Bu group, the conformer $\mathbf{B}$ should be strongly disfavored because of the increased repulsive interaction between the $t-\mathrm{Bu}$ group and the double bond. In the case of conjugated ( $Z$ )-ester $\mathbf{1 b}$. the $\overline{\mathrm{K}}$-inside conformer $\mathbf{C}$ would be unfavorable owing to the severe steric hindrance between the methosy carbonyl group and the $N$-Boc group. Therefore. the conjugated ( $Z$ )-ester $\mathbf{1 b}$ in Table 1 resulted in poor selectivity. The $s m$-selectivity with some ( $Z$ )-olefins have been reported in literature. ${ }^{\text {sb }} \mathrm{s}(\mathrm{ch}$

With the above results in hand, we wanted to apply the diastereoselective dilydroxylation reaction to the conjugated (E)-ester $\mathbf{1 0}$ with an OBO ester group in the alkyl chain. Since the OBO ester is a bulky group similar to the $t$-Bu group, a high diastereoselectivity of the dihydroxylation would be expected under the same reaction conditions. Moreover, the OBO ester group can be readily functionalized to a carboxylic acid or the acid derivatives such as an alcohol or an amine. If the desired high selectivity could be achieved, several interesting bioactive compounds with an amino diol unit would be efficiently prepared. Although the OBO ester group has been utilized for some diastereoselective reactions, it has not been utilized as a stereodirecting group in the $\mathrm{OsO}_{4}$-catal-

Scheme 3. Dihydroxylation of conjugated ( $E$ )-ester $\mathbf{1 0}$ and determination of the relative stereochemistry.
yzed dihydroxylation reactions to date. ${ }^{11}$
An 1 -Cbz derivative of ( $E$ )-3.4-didehydroglutamate OBO ester 10 was prepared from commercially available $N$-Cbz-Lserine 6 with a slight modification from the reported procedure (Scheme 2). ${ }^{91}$ After a selective protection of the primary alcohol of 6 with a TBS group, a DCC-mediated coupling of the carboxylic acid of 7 with (3-methyl-3-oxetanyl) methanol produced oxetany lmethyl ester 8 in excellent yield. The esterification step required only a stoichiometric amount of (3-methyl-3-oxetanyl)methanol. Then compound 8 was treated with $\mathrm{BF}_{3} \cdot \mathrm{OEt}_{2}$ to give the OBO ester functionality of 9 with concomitant deprotection of the TBS group. The above modified procedure for the OBO ester formation did not require excessive amount of the rather expensive alcohol ${ }^{11 a}$ or conversion of the oxetanylalcohol into its tosylate before the esterfication step. ${ }^{116 \%}$ Moreover. the desired oxetanylmethyl ester was prepared in ligher yield and shorter reaction time. A Swern oxidation of OBO ester 9 followed by a Wittig olefination with the corresponding stabilized ylide provided the desired conjugated ( $E$ - -ester 10.

The $\mathrm{OsO}_{+}$-catalyzed dihydroxylation of $\mathbf{1 0}$ was conducted under the same conditions as shown in Scheme 1 (Scheme 3). The resulting amino diol was isolated in $94 \%$ yield but the diastereomeric ratio of the diol product was difficult to be determined because of the some broad peaks in its ${ }^{1} \mathrm{H}-\mathrm{NMR}$ spectnim. After acetylation of the crude diol product the diastereomeric ratio was shown to be more than $12.5: 1$ by ${ }^{1} \mathrm{H}$ NMR and GC/MS analyses of diacetate 11. To confirm the relative configuration of the new stereogenic centers with the hydroxyl groups, we tried to convert diacetate 11 into the corresponding $\gamma$-lactam as shown in Scheme 1. However. some unknown side reactions occurred during the cyclization reaction of 11 to cause a low yield of the corresponding $\gamma$ lactam. Fortunately a cyclization reaction of the TBS-protected amino diol 12 gave only the major isomer of the desired $\gamma$-lactam 13. 13trans. The measured coupling constant $J_{4.5}$ of 13 trans was 5.7 Hz , which indicated that the major isomer was the trans isomer at $\mathrm{C}-4$ and $\mathrm{C}-5$ although the minor isomer of $\mathbf{1 3}$ could not be isolated. The $O$-Ac derivative of the major isomer of the $\gamma$-lactam. obtained from 11 as mentioned above, also had the similar $J_{4.5}$ value of 5.8 Hz . An unambiguous assignment of the relative stereochemistry was esta-

Scheme 4. Synthesis of the target compound 15 from 13.
blished after conversion of the major isomer of $\mathbf{1 3}$ into one of our target compounds 15. a bioactive $\alpha$-glucosidase inhibitor (see below Scheme 4).

It should be noted that the observed selectivity for the anti isomer ( $>12.5: 1$ ) in the present study is a much improved result. The reported diastereoselectivities from the $\gamma$-amino- $\alpha$, $\beta$-unsaturated ( $E$ )-esters with an $\hat{\beta}$-Boc or $N$-Cbz group were not consistent and useful. ${ }^{3}$ Especially. the serine-derived $\gamma$ -amino- $\alpha . \beta$-unsaturated $(E)$-esters and ketones gave the mixed results ranging from 1:1.9 to 6:1 of an anti:sw ratio. ${ }^{12}$ It is also interesting to note that the selectivity obtained from compound 10 is comparable to that of the $\gamma$-amino- $\alpha, \beta$-unsaturated (E)-ester $($ anti:sw $=13: 1)$ with a 2 -ary loxazoline group in the alkyl chain, which was possible only with the chiral AD -mix$\beta$ reagent used. ${ }^{126}$

The potential applications of the present method are an efficient and highly stereoselective synthesis of natural and unnatural compounds with an amino diol unit such as 3.tdihy droxyglutamic acid. ${ }^{8,} 3.4$-di-epi-polyoxamic acid. ${ }^{13} \mathrm{~d}$ iminoarabinitol ${ }^{14}$ and a key structural motif found in sphingosine analogs. ${ }^{15}$ As an example. Scheme + shows a straightforward conversion of $\gamma$-lactam 13 into a chiral azasugar 2pyrrolidinone 15, an $\alpha$-glucosidase inhibitor. Thus. the OBO ester group of $\mathbf{1 3}$ was hydrolyzed under acidic conditions and then, the resulting ester group was reduced by $\mathrm{LiBH}_{4}$ to afford the primary alcohol of 14 in $91 \%$ yield. Finally, deprotection of the TBS groups gave ( $3 S, 4 R .5 R$ )-3,4-dihydroxy- 5 -hy-droxymethyl-2-pyrrolidinone 15 . The NMR spectrum and optical rotation value well matched those reported in literature. ${ }^{16}$ Thus. it established unequivocally the relative stereochemistry of 13 trans.

In conclusion we have found that the $\mathrm{OsO}_{4}$-catalyzed dilydroxylation reactions of the monosubstituted allylic amine and the $\gamma$-anmino- $\alpha, \beta$-unsaturated-( $E$ )-esters with a bulky group in the alkyl chain provide a high anti-selectivity even with versatile N -acyloxy protecting groups such as a N -Boc or $\mathrm{N}-\mathrm{Cbz}$ group. The high selectivity was also possible even without addition of chiral agents. Therefore the OBO ester group in the alkyl chain of the conjugated $(E)$-ester 10 was proved to be a functionalized stereodirecting group in the $\mathrm{OsO}_{4}$-catalyzed dihydroxylations. The potential of the present method was demonstrated by an efficient conversion of the key $\bar{l}$-Boc or $\hat{M}$-Cbz intermediate 12 into one of the target compounds 15, an $\alpha$-glucosidase inhibitor. Its further synthetic applications to other bioactive target compounds are currently underway in our lab.

## Experimental Section
