**Abstract:** A 23-year-old female residing in a village of Cao Bang Province, North Vietnam, visited the Hospital of Hanoi Medical University in July 2013. She felt dim eyes and a bulge-sticking pain in her left eye for some days before visiting the hospital. In the hospital, a clinical examination, an eye endoscopy, and an operation were carried out. A nematode specimen was collected from the eye of this patient. The body of this worm was thin and long and measured 22.0×0.3 mm. It was morphologically suggested as an immature female worm of *Angiostrongylus cantonensis*. By a molecular method using 18S rRNA gene, this nematode was confirmed as *A. cantonensis*. This is the first molecular study for identification of *A. cantonensis* in Vietnam.

**Key words:** *Angiostrongylus cantonensis*, eosinophilic meningoencephalitis, eye

## INTRODUCTION

In the genus *Angiostrongylus*, a total of 21 species have been described, including 2 species which cause diseases in humans such as *Angiostrongylus cantonensis* and *Angiostrongylus costaricensis* [1,2]. *A. cantonensis* causes eosinophilic meningoencephalitis in humans damaging the brain tissues, which result in bleeding, inflammation, and granuloma formation [1]. Neurological symptoms vary with the region affected. On the other hand, *A. costaricensis* causes abdominal infections [2].

*A. cantonensis* was first found from the lungs of rats *Rattus norvegicus* and *Rattus rattus* in 1935 by Chen in China [2]. The first human case infected with *A. cantonensis* was reported by Nomura and Lin in 1945 in Taiwan [2]. In 1962, Rosen et al. [3] reported 2 cases of eosinophilic meningoencephalitis caused by *A. cantonensis* and called the worm as the rat lung-worm. After then, *A. cantonensis* has been detected in Madagascar, Hawaii, South East Asia, and Japan [2]. Meanwhile, *A. costaricensis* was detected for the first time in Costa Rica, and then in Middle America and North America [2].

In Vietnam, eosinophilic meningoencephalitis caused by *A. cantonensis* was first detected in 1976 [4]. Phan [4] reported 2 human cases (3- and 7-year old) with symptoms like fever, vomiting, snatched legs, leg pain, paralyzes, positive meningoencephalitis, and eosinophilia (29-59%). In addition, An [5] reported 15 children cases (1-15 years old) of eosinophilic meningoencephalitis due to *A. cantonensis* infection in the National Children Hospital during 1995-2000. After then, De et al. [6,7] reported 5 cases of angiostrongyliasis in 2004 and another case in 2008. We report here an additional case of human angiostrongyliasis caused by *A. cantonensis*; the species was molecularly confirmed for the first time in Vietnam.

## CASE RECORD

The patient was a 23-year-old female residing in the Chi Thao Village, Quang Yen District, Cao Bang Province, North Vietnam. In July 2013, she felt dim eyes and a bulge-sticking pain in her left eye for some days at home. She visited the provincial hospital and then the Hospital of Hanoi Medical University, Hanoi, Vietnam. In the hospital, a clinical examination and an eye endoscopy were carried out, and a nematode worm was seen in the left eye. This nematode specimen was collected from the eye of this patient by operation. The body of this worm was thin and long and measured 22 mm in length and 0.3 mm in width (Fig. 1). It was morphologically suggested as

an immature (female) worm of *A. cantonensis*.

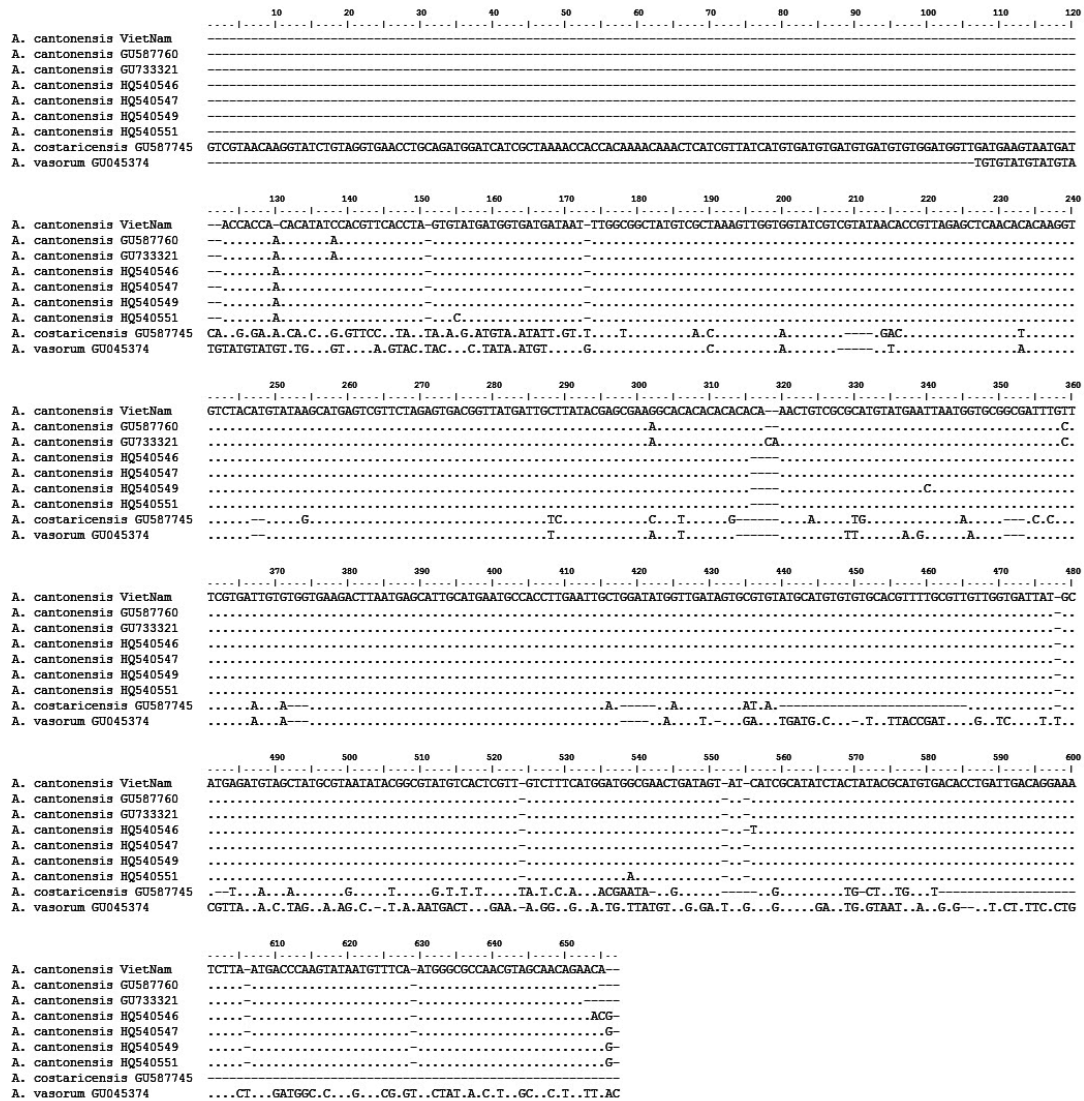

By the molecular method using a portion of 18S *rRNA* gene, this Vietnamese *Angiostrongylus* was sequenced and compared with different worldwide *A. cantonensis* isolates from GenBank (Table 1). A comparison was made on 522 nucleotides of a portion of 18S *rRNA* gene between the Vietnamese *Angiostrongylus* and isolates from USA (AC-NO), Brazil (AC-BR), China (AC-SZ1, AC-SZ2, AC-QY, and AC-WZ), Costa Rica (AC-CR), and UK (AV-UK). The results revealed 99% identity with other *A. cantonensis* reported in GenBank (Fig. 2).

## DISCUSSION

The symptoms in angiostrongyliasis patients in Vietnam included headache (15/15), fever (12/15), vomiting (11/15), harden neck (8/15), and eosinophilia (31.5-48.5%) [4]. In 2004, De et al. [6] also reported 5 cases (19-month to 10-year-old) of angiostrongyliasis with the symptoms of headache (5/5), fever (5/5), vomiting (4/5), snatched leg (5/5), disordered reflected knee (5/5), leg paralysis (5/5), positive meningoencephalitis (5/5), eosinophilia (5/5 with 19-30%), and

positive ELISA with *Angiostrongylus* antigen (5/5). A worm was collected from 1 of the 5 patients [6]. These symptoms were similar to those reported previously in Taiwan [8]. However, eosinophilic meningoencephalitis due to *A. cantonensis* occurred more and more often in Vietnam [7]. The parasitic place of *Angiostrongylus* was usually the brain, but can be in other places, including the eyes. In 2001, Xuan et al. [9] also reported a case infected with *A. cantonensis* in the eye.

The incidence of ocular angiostrongyliasis is low; however, it can cause hypopsia or even vision loss, which would seriously affect the quality of the life of patients [10]. Feng et al. [10] reviewed total 42 ocular cases reported worldwide; nearly a half of them were from Thailand and the rest were from other Asian countries, including Sri Lanka, India, Taiwan, Vietnam, Malaysia, Japan, and Indonesia. In most cases, worms were found from the anterior chamber or vitreous fluid, and in a few cases they were from the retina or subretina [10]. The majority of the ocular cases was not associated with cerebrospinal symptoms; only 12 of the 42 cases suffered from eosinophilic meningitis [10]. In our case, the patient felt dim eyes and a bulge-sticking pain in her left eye; however, she developed no further symp-

**Fig. 2.** Comparison of 522 nucleotides of a portion of 18S ribosomal RNA gene (*18S rRNA*) between the Vietnamese *Angiostrongylus cantonensis* and isolates from USA (AC-NO), Brazil (AC-BR), China (AC-SZ1, AC-SZ2, AC-QY, AC-WZ), Costa Rica (AC-CR), and UK (AV-UK). Note similarities between the Vietnamese (*A. cantonensis* Vietnam) and other isolates. Mark (.) is similar to each other in nucleotides; mark (-) is mismatching.

toms like meningoencephalitis. After the surgical removal of the worm, her eye symptoms completely disappeared.

The phylogenetic tree of *A. cantonensis* Vietnam and other strains from different countries targeting a part of *18S rRNA* nucleotide sequences was constructed by the neighbor-joining (NJ) method using MEGA4.0 [11]. It has been shown that the Vietnamese *A. cantonensis* is located in the same group with other *A. cantonensis* isolates available in GenBank (Fig. 3). The present study is the first to identify the species of the nematode by a molecular method in Vietnam.

**ACKNOWLEDGMENTS**

This research was funded by Vietnam National Foundation for Science and Technology Development (NAFOSTED) under grant no. 106-YS.05-2014.08, and collaborated with the National Hospital of Eyes, Hanoi, Vietnam.

**CONFLICT OF INTEREST**

We have no conflict of interest related to this work.
