Influencing Factors Analysis of Facial Nerve Function after the Microsurgical Resection of Acoustic Neuroma

WenMing Hong, M.D.,¹ HongWei Cheng, M.D.,¹ XiaoJie Wang, M.D.,² ChunGuo Feng, M.D.³
Departments of Neurosurgery,¹ Pathology,² Neurosurgery,³ First Affiliated Hospital, AnHui Medical University, Hefei, China

Objective: To explore and analyze the influencing factors of facial nerve function retention after microsurgery resection of acoustic neuroma.

Methods: Retrospective analysis of our hospital 105 acoustic neuroma cases from October, 2006 to January 2012, in the group all patients were treated with suboccipital sigmoid sinus approach to acoustic neuroma microsurgery resection. We adopted researching individual patient data, outpatient review and telephone followed up and the House-Brackmann grading system to evaluate and analyze the facial nerve function.

Results: Among 105 patients in this study group, complete surgical resection rate was 80.9% (85/105), subtotal resection rate was 14.3% (15/105), and partial resection rate 4.8% (5/105). The rate of facial nerve retention on neuroanatomy was 95.3% (100/105) and the mortality rate was 2.1% (2/105). Facial nerve function when the patient is discharged from the hospital, also known as immediate facial nerve function which was graded in House-Brackmann: excellent facial nerve function (House-Brackmann I-II level) cases accounted for 75.2% (79/105), facial nerve function III-IV level cases accounted for 22.9% (24/105), and V-VI cases accounted for 1.9% (2/105). Patients were followed up for more than one year, with excellent facial nerve function retention rate (H-B I-II level) was 74.4% (58/78).

Conclusion: Acoustic neuroma patients after surgery, the long-term (≥1 year) facial nerve function excellent retaining rate was closely related with surgical proficiency, post-operative immediate facial nerve function, diameter of tumor and whether to use electrophysiological monitoring techniques; while there was no significant correlation with the patient’s age, surgical approach, whether to stripping the internal auditory canal, whether there was cystic degeneration, tumor recurrence,whether to merge with obstructive hydrocephalus and the length of the duration of symptoms.

Key Words: Acoustic neuroma · Facial nerve function · Sigmoid sinus approach · Electrophysiological monitoring · Keyhole · Internal acoustic meatus.

INTRODUCTION

Acoustic neuroma which mostly originates from vestibulocochlear nerve is the most common tumor in the cerebellopontine angle (CPA), also known as vestibular nerve Schwann cell tumor, and less than 10% of the tumor originate in the cochlear nerve. Acoustic neuroma accounting for 85–92% of cerebellopontine angle tumors, accounted for 93.1% of intra-
cranial nerve Schwann cell tumor, and accounting for 7.79–
10.64% of intracranial tumors. With the growth of tumor, it
can be oppressive to the outer side of the pons and the leading
ege of the cerebellum, which caused cerebellopontine angle
tumor syndrome which included hearing changes, tinnitus,
vestibular dysfunction, headache, cerebellar ataxia and dys-
fuction of facial nerve, trigeminal nerve and posterior group
cranial nerve, etc. Moreover, it can lead to serious damage to
the life quality of the patients, even endanger patient safety.
The cerebellopontine angle is a triangular space area com-
posed by cerebellum, pons and oblongata and petrous bone
(internal auditory meatus), and it is located in the both sides
of posterior cranial fossa anterior. The triangular area has
trigeminal nerve, vestibulocochlear nerve, glossopharyngeal
nerve, vagus nerve and accessory nerve from top to bottom;
from the outside to the inside is vestibulocochlear nerve, laby-
rinthine artery, anterior inferior cerebellar artery and abdu-
cent nerve, facial nerve. Acoustic neuroma is located in this
space, because the region is deep, and has many important
structures, and specifically closely related with pons, cerebel-
num and posterior cranial nerves, which makes the treatment
of acoustic neuroma face huge challenge to cut all tumour and
protect neural function. Operation treatment mainly con-
tained three kinds of operation approach: suboccipital retro-
sigmoid approach (RSC), the middle cranial fossa approach
(MFC), translabyrinthine approach (TLC), in which the RSC
could show a wide range, so it is for all kinds of the size of the
tumor, and the total removal rate is was high. Also, the inter-
nal auditory canal can be opened according to the actual
needs, which is easy to early identification facial nerve from
the internal auditory canal. Therefore, many neurosurgeons
used this surgical approach.

In recent years, there is no apparent difficulty for acoustic
neuroma resection with the development of microsurgical
technique, endoscope, neural electrophysiological monitoring
and neuronavigation technique. Difficulties and challenges of
operation are how to obtain the maximum tumor resection
while at the same time to get the surrounding normal tissue
maximum protection, and long-term retention of facial nerve
function. The authors collected total of 105 cases with acous-
tic neuroma cases from October 2006 to January 2012, with
78 patients with long-term follow-up as the main research ob-
ject to explore the influence factors of facial nerve function
retention after acoustic neuroma microsurgery excision in
suboccipital retrosigmoid approach.

**MATERIALS AND METHODS**

**General case information**

From October 2006 to January 2012, we retrospectively
analyzed the 105 cases of acoustic neuroma operation patients
in the department of neurosurgery in our hospital. In this
group, we found the patients’ age was from 14 to 73 years old,
the average age was 48.7 years old; male was 41 cases, female
was 64 cases; the left acoustic neuroma was 59 cases, right side
was 46 cases. Preoperative symptom duration time was from 1
to 360 months, average was 42 months. Large acoustic neuro-
oma (diameter ≥30 mm) accounted for 90.5% (95/105). In this
study group, complete surgical resection rate was 80.9%
(85/105), subtotal resection rate was 14.3% (15/105), and partial
resection rate was 4.8% (5/105). The rate of facial nerve retain-
ment on neuroanatomy was 95.3% (100/105) and the mortality
rate was 2.1% (2/105). At the end of follow-up, 3 cases had tu-
mor recurrence. All patients routine taken orally nimodipine
tablets (1# Tid), mecobalamin tablets (1# Tid), more than three
months. We followed up 78 cases whose long-term facial nerve
function means follow-up time ≥1 year in the group. The 78
cases were as the main study object to explore the influencing
factors as the main study object to explore the influencing
factors of facial nerve function.

**Clinical manifestations**

There were a total of 71 patients (91%) with hearing impair-
ment as a typical clinical presentation; 34 cases (43.6%) with
facial numbness; 10 cases (9.52%) with facial nerve dysfunc-
tion; 20 cases (25.6%) in performance of headache and dizzy-
ness symptoms; 15 cases (14.6%) with muscle strength de-
creased; 25 cases (23.9%) with ataxia; 12 cases (15.4%) showed
hoarseness and dysphagia; and 5 cases (6.4%) with vision re-
duced.

**Imaging manifestations**

All patients before operation were performed head MRI ex-
amination, in which 69 cases underwent brain CT examina-
tion, 78 cases with internal auditory canal plain film examina-
tion. In 69 patients examined by cranial CT cases, 7 cases
showed low density lesions, 26 cases showed a high density or
slight high density, 36 cases showed mixed density. The size of the tumor: 7 cases with diameter less than 30 mm; 18 cases’ diameter was 30–39 mm; 27 cases’ diameter was 40–49 mm, 26 cases’ diameter was more than 50 mm. In the 78 cases with internal auditory canal radiographs, 67 cases showed internal auditory canal enlargement. Acoustic neuroma in T1 weighted magnetic resonance images showed isointensity or slightly longer signal, T2 weighted magnetic resonance imaging showed isointensity or slightly longer signal. The study group of patients with MRI, CT and internal auditory canal radiography showed that 36 cases with supratentorial ventricles expanded (46.2%), 67 cases with the internal auditory canal enlarged (64.1%), 3 cases with acoustic neuroma expand to the middle cranial fossa (3.8%).

Surgical methods

The patients were treated by suboccipital retrosigmoid approach to resect tumors. Five patients with large tumors (>6.0 cm) had hydrocephalus and tonsillar hernia, so emergency ventricular puncture and drainage to reduce intracranial pressure were performed before craniotomy operation. After satisfactory anesthesia, patients were in the lateral decubitus position, the head elevated 15°, slightly deflect to the uninjured side, mastoid medial edge at the highest point, occipital squama is the horizontal part, operation incision was 1.5 cm to the inside of star point, and longitudinal incision was 6 cm long. We drilled a bone window about 2.5–3 cm to the mastoid rear in keyhole approach, whose upper outer edge to the transverse sinus and outer edge to the sigmoid sinus; while the bone flap diameter of conventional craniotomy expanded to about 4.5 cm. The operation microscope was placed after the dura mater was cut parallel to the bone window edge of “1” shape, then open the arachnoid to slowly released cerebrospinal fluid and use mannitol to reduce brain pressure. After cerebellar hemisphere retraction and operative field fully exposed, we handled the arachnoid and the tumor. We paid special attention to avoid injury of facial nerve and to protect important vascular in this stage. In the tumor treatment after filling on crossing tumors Internal auditory canal should be grinded if the tumor growth is inward to internal auditory canal. Patients were treated by routine craniotomy were 21 cases, while the keyhole craniotomy were 57 cases; 53 cases with monitoring of electrophysiology; 31 cases with internal auditory meatus removal.

Methods of follow-up and facial nerve function's evaluation

All patients were followed with careful review of medical records including symptoms, neurological signs, imaging data and questionnaire. Evaluation of facial nerve function is based on control of facial expressions (including five independent, eyes closed, gills drums, whistles, teeth, wrinkled forehead), and control of facial symmetry in the resting and movement state. The results associated with the classification of facial nerve function were based on House-Brackmann grading system. All data were handled by SPSS version 18.0 for statistical analysis (SPSS Inc., Chicago, IL, USA), and p<0.05 was considered statistically significant.

This table shows the relation between facial nerve function of postoperative long-term (>1 year) and early facial nerve function, using Spearman correlation analysis indicated: the early postoperative facial nerve function and long-term facial nerve function shows close correlation (correlation coefficient r=0.702, p<0.05). H-B: House-Brackmann
RESULT

The relationship between facial nerve function of postoperative long-term (>1 year) and early facial nerve function (Table 1)

The relationship between tumor size and long-term postoperative facial nerve function (Table 2)

Tumors were divided into four groups according to the diameter: 1) <30 mm; 2) 30–39 mm; 3) 40–49 mm; 4) >50 mm. 7 cases with the tumor diameter of 30 mm; 18 cases with the tumor diameter of 30–39 mm; 27 cases with the tumor diameter of 40–49 cm, 26 cases with the tumor diameter more than ≥50 mm.

The relationship between intraoperative electrophysiological monitoring and postoperative long-term facial nerve function (Table 3)

According to whether use of intraoperative neurophysiological monitoring, the study group was divided into two groups: monitoring group and non monitoring group. The monitoring group was 53 cases; no monitoring group was 25 cases, and the details were shown in Table 3.

The relationship between tumor recurrence and long-term facial nerve function

According to whether the patients with recurrence of tumor, the study cases were divided into two groups: 75 cases without tumor recurrence; 3 cases with tumor recurrence. Details of the relationship between tumor recurrence and the postoperative long-term facial nerve function were shown in Table 4.

The relationship between tumor cystic degeneration and long-term postoperative facial nerve function

According to whether the tumor cystic degeneration, the study cases were divided into two groups: 35 cases with tumor cystic degeneration; 43 cases without tumor cystic degeneration. Details of the relationship between tumor cystic degeneration and the postoperative long-term facial nerve function were shown in Table 5.

The relationship between surgical approach and long-term postoperative facial nerve function

According to the surgical approach, the study cases were divided into two groups: routine craniotomy were 21 cases, while the keyhole craniotomy were 57 cases. Details of the relationship between surgical approach and long-term postoperative facial nerve function were shown in Table 6.

The relationship between grind internal acoustic meatus and long-term postoperative facial nerve function

According to whether grind the internal acoustic meatus, the study cases were divided into two groups: 35 cases with grinding the internal acoustic meatus, while 43 cases without grinding. Details of the relationship between grind internal acoustic meatus and long-term postoperative facial nerve function were shown in Table 7.

The relationship between obstructive hydrocephalus and long-term postoperative facial nerve function

According to whether the patients with obstructive hydrocephalus, the study cases were divided into two groups: 36 cases with obstructive hydrocephalus, while 42 cases without obstructive hydrocephalus. Details of the relationship between obstructive hydrocephalus and long-term postoperative facial nerve function were shown in Table 8.

The relationship between patients’ age and long-term postoperative facial nerve function

According to the patients’ age, the study cases were divided into four groups: 1) 0–20 years old, 2) 21–40 years old, 3) 41–60 years old, and 4) >60 years old. Details of the relationship between patients’ age and long-term postoperative facial nerve function were shown in Table 9.

The relationship between duration of symptoms before surgery and long-term postoperative facial nerve function

According to the duration of symptoms before surgery, the study cases were divided into four groups: 1) ≤24 months, 2) 25–48 months, 3) 49–72 months, and 4) ≥72 months. Details of the relationship between duration of symptoms and long-term postoperative facial nerve function were shown in Table 10.

DISCUSSION

Each patient was evaluated every three months. We evaluated the facial nerve function of all follow-up outpatients and kept records with digital photo mode.

In this study, through the case retrieval, and combined with

The data were used the ordinal data linear trend test analysis, and the result suggests that there is no statistically significant difference in the excellent rate of long-term postoperative facial nerve function between the groups ($\chi^2=2.382, p=0.984$). It indicates that there is no significant correlation between duration of symptoms before surgery and long-term postoperative facial nerve function. H-B : House-Brackmann

the related literature, we found that complete tumor resection was the key point to avoid the recurrence of the tumor after operation, and also to avoid second injury of facial nerve function after the operation of the recrudescent tumor. Tumor recurrence often face the operation once again, which may further increase the damage of facial-acoustic nerve and lead to more serious injury of facial nerve function. But in our study, the data showed that there was no obvious statistical difference between tumor recurrence group and non-recurrence group in long-term postoperative facial nerve function ($p=0.340$). The reasons for this phenomenon may be, first, operating skill of the surgeon. If the surgeon had good operating skill, the second operation did not increase the injury of facial nerve function. Second reason may be the small number of cases, so the extrapolation of the study was unknow. At the same time, we found that postoperative facial nerve anatomy retention rate was high (95.3%), but the rate of postoperative excellent facial nerve function (House Brackmann I-II) was only 75.2% (79/105), which was to say the facial nerve function and facial nerve anatomy retention rate were not necessarily in the same level. Investigate its reason may be that: first, some electric coagulation thermal injury of facial nerve could make its anatomy seem normally in the operation, but its function may have been damaged; second, some blood vessels for nutrition nerve may not be protected well during operation, which may cause postoperative nerve injury of ischemia and hypoxia. We know that cerebral vascular distribution is important to the nerve function. Therefore, when the tumor resection underwent retrosigmoid approach, we should pay attention to the following problems: 1) in the process of separating the tumor and pons, we must be always along the two tissue interface, first to separate arachnoid of tumor surface while must protect peripheral nerve and blood vessel. Then block resection in tumor capsule, but it must not be forced to pursue a full cut, otherwise easily lead to brain stem injury; 2) do not use electrocoagulation random, and we must flush cooling with saline when use bipolar coagulation to in order to avoid heat damage of peripheral nerve tissue; 3) open brain cistern to release cerebrospinal fluid was very important, the operation steps need to be patient, must make full retraction of cerebellum and slightly pull that can reveal the cerebellopontine angle and get enough operation space; and 4) the operator must have good technology of neurosurgery operation.

As to the choice of surgical approach, the trend is minimally invasive operation, while the keyhole technology is a symbol of minimally invasive neurosurgery. The keyhole operation was guaranteed implementation along with the development of endoscopy and navigation technology. In the process of craniotomy, bone window less than 3 cm is called the keyhole which is direct and accurate path and could avoid excess of craniotomy part in routine operation, as far as possible to arrived at the lesion site non-invasively and not exposed no lesion area. The advantages of keyhole: 1) the skin incision is small, which can maximize the retention of the patient’s appearance; 2) cranial window range is small, which can reduce excess of craniotomy part so as to minimize the normal brain tissue exposure and interference; 3) the path is direct and accurate and made full use of normal intracranial anatomy space, which can reduce the traction of brain, postoperative brain edema, brain contusion, and even the incidence of intracerebral hematoma; 4) it also reduces postoperative epilepsy, bleeding and other complications. And the postoperative reaction was light, patients are quickly recover, cost is low with
good effect. Some research had shown that posterior suboccipital keyhole approach is more effective than conventional surgical approach in treatment of the cerebellopontine angle lesions. But our study showed that there was no statistically significant difference in the excellent rate of long-term postoperative facial nerve function between routine craniotomy group and keyhole craniotomy group ($p=0.911$).

Further studies showed that tumor volume was related with the effect of operation\textsuperscript{[13,18,22,23,26]}. The foreign bulk case studies\textsuperscript{[5,6]} displayed that if the tumors were smaller, the postoperative facial nerve function was better. From 78 follow-up cases of this group, we can see that the excellent rate of long-term facial nerve function ($\geq 1$ years after operation) would decline, as the tumors’ volume increased, which showed statistical significance between postoperative long-term facial nerve function and tumor’s diameter ($p=0.001$). It also coincided with the foreign related research.

In addition, with the progress of science and technology, the electrical physiological monitoring technology constantly applied to the operation of neurona\textsuperscript{[28]}. This technique helps to improve the rate of facial nerve preservation. Some studies\textsuperscript{[20,29]} have also suggested that monitoring of facial EMG in surgery can help surgeon early identify the walking direction of the facial nerve, and confirm whether the facial nerve structure was complete after facial nerve tumor resection, which had important significance to the retention of the facial nerve function. According to whether use of intraoperative neurophysiological monitoring, the study group was divided into two groups: monitoring group and non monitoring group. Through the data comparison, the excellent rate of postoperative long-term facial nerve function with electric physiological monitoring was significantly higher than those patients without the use of electrophysiological monitoring. It also confirmed the positive significance of the electrophysiological monitoring at home and abroad.

From the literature review, we found that foreign data showed postoperative long-term function of facial nerve was related with and cystic change of acoustic neurona, obstructive hydrocephalus, preoperative radiotherapy and postoperative vasopressor therapy to patients\textsuperscript{[1,0,13,19,24,26,27]}. However, our study data showed that there was no statistical significance with cystic change and hydrocephalus ($p=0.05$). As to the preoperative radiotherapy, the research was unable to confirm the correlation of postoperative long-term function of facial nerve and preoperative radiotherapy due to all patients without radiotherapy before surgery.
