Abstract. Let \( f = h + \overline{g} \) be a normalized harmonic mapping in the unit disk \( D \). In this paper, we obtain the sharp radius of univalence, fully starlikeness and fully convexity of the harmonic linear differential operators \( D_{\epsilon} f = z f' - \epsilon f'' \) \((|\epsilon| = 1)\) and \( F_{\lambda}(z) = (1 - \lambda) f + \lambda D_{\epsilon} f \) \((0 \leq \lambda \leq 1)\) when the coefficients of \( h \) and \( g \) satisfy harmonic Bieberbach coefficients conjecture conditions. Similar problems are also solved when the coefficients of \( h \) and \( g \) satisfy the corresponding necessary conditions of the harmonic convex function \( f = h + \overline{g} \). All results are sharp. Some of the results are motivated by the work of Kalaj et al. [8].

1. Introduction

Throughout this paper, let \( \mathcal{H} \) denote the class of all complex-valued harmonic functions \( f = h + \overline{g} \) defined on the unit disk \( \mathbb{D} = \{ z \in \mathbb{C} : |z| < 1 \} \) normalized by \( f(0) = 0 = h(0) = h'(0) - 1 \), where \( h \) and \( g \) are analytic in \( \mathbb{D} \) such that

\[
(1.1) \quad h(z) = z + \sum_{n=2}^{\infty} a_n z^n \quad \text{and} \quad g(z) = \sum_{n=1}^{\infty} b_n z^n.
\]

Also, let \( \mathcal{H}_0 = \{ f = h + \overline{g} \in \mathcal{H} : g'(0) = 0 \} \) and \( J_f(z) = |h'(z)|^2 - |g'(z)|^2 \) denote the Jacobian of \( f = h + \overline{g} \). According to Lewy’s theorem (see [9] or [5]), \( f \in \mathcal{H} \) is locally univalent and sense-preserving if and only if \( J_f(z) > 0 \) in \( \mathbb{D} \), i.e., \( |g'(z)| < |h'(z)| \); or equivalently, the dilatation \( \omega(z) = g'(z)/h'(z) \) is analytic in \( \mathbb{D} \) with \( |\omega(z)| < 1 \) in \( \mathbb{D} \). Note that if \( f \in \mathcal{H}_0 \), then it is clear that \( \omega(0) = 0 \). Let \( \mathcal{S}_H \) denote the class of univalent and sense-preserving functions \( f = h + \overline{g} \in \mathcal{H} \). The class \( \mathcal{S}_H \) for which \( g(z) \equiv 0 \) reduces to the class \( \mathcal{S} \) of normalized univalent analytic functions in \( \mathbb{D} \). This is fundamental in the study of univalent functions theory. The geometric subclasses of \( \mathcal{S}_H \) consisting of the

©2018 Korean Mathematical Society
convex, starlike and close-to-convex functions in $\mathbb{D}$ are denoted by $C_H$, $S_H^*$ and $K_H$, respectively. It is a standard practice to let

$$S_H^0 := S_H \cap H_0, \quad C_H^0 := C_H \cap H_0, \quad S_H^{0*} := S_H^* \cap H_0, \quad K_H^0 := K_H \cap H_0.$$ 

We now recall one of the results of Clunie and Sheil-Small [3] which connects analytic close-to-convex functions with that of harmonic close-to-convex functions.

**Theorem A.** Suppose that $h$ and $g$ are analytic in $\mathbb{D}$ with $|g'(0)| < |h'(0)|$ and $h + \epsilon g$ is close-to-convex for each $\epsilon$, $|\epsilon| = 1$. Then $f = h + \bar{g}$ is close-to-convex in $\mathbb{D}$.

As an analog of Bieberbach Conjecture proved by de Branges [4] for functions in $S$, Clunie and Shell-Small [3] proposed the following conjecture for functions in $S_H^0$.

**Conjecture A.** Let $f = h + \bar{g} \in S_H^0$, where the representation of $h$ and $g$ are given by (1.1) with $b_1 = 0$. Then for each $n \geq 2$,

$$|a_n| \leq \frac{1}{6}(2n+1)(n+1), \quad |b_n| \leq \frac{1}{6}(2n-1)(n-1) \quad \text{and} \quad |a_n - b_n| \leq n.$$ 

Equality holds for the harmonic Koebe function defined by

$$K(z) = H_1(z) + G_1(z) = \frac{z - \frac{1}{2}z^2 + \frac{1}{6}z^3}{(1 - z)^3} + \frac{\frac{1}{2}z^2}{(1 - z)^2}.$$ 

Conjecture A has been verified for certain special situations, e.g. for the family $S_H^{0*}$ and the family of typically real functions in $\mathbb{D}$ by Clunie and Sheil-Small [3] himself, for the family of functions that are convex in one direction by Sheil-Small [14], and for the close-to-convex family $K_H^0$ by Wang, Liang and Zhang [15]. More about harmonic mappings may be obtained from the monograph of Duren [5] and the survey article of Ponnusamy and Rasila [11]. For a recent development on Conjecture A for functions in $S_H^0$, we refer to the recent article of Ponnusamy et al. [12].

Also in [3], Clunie and Sheil-Small proved that if $f = h + \bar{g} \in C_H^0$, then

$$|a_n| \leq \frac{n+1}{2} \quad \text{and} \quad |b_n| \leq \frac{n-1}{2}$$

hold for all $n \geq 2$. Equality holds for the harmonic right half-plane mapping $L \in C_H^0$ given by

$$L(z) = H_2(z) + G_2(z) = \frac{z - \frac{1}{2}z^2}{(1 - z)^2} + \frac{\frac{1}{2}z^2}{(1 - z)^2}.$$ 

Our present article is motivated by the recent work of Kalaj et al. [8] and also by the results known in the analytic case. Accordingly, we are mainly concerned with certain class of (sense-preserving harmonic) functions $f = h + \bar{g} \in H_0$ satisfying the condition (1.2) or (1.4).
Definition 1. Let $F \subset \mathcal{H}$, where $F = S_H$ or $S_0^H$; $F = C_H$ or $C_0^H$; $F = K_H$ or $K_0^H$ etc.. For $r \in (0, 1)$, we say that $f = h + g \in F$ in $|z| < r$ if $f_r(z) = r^{-1}f(rz) \in F$ in $|z| < 1$ in the usual sense.

For example, we say that $f \in S_0^H$ in $|z| < r$ whenever $f_r \in S_0^H$ (in $|z| < 1$).

This convention will be followed throughout this article.

The class $\mathcal{R}$ given by

$$\mathcal{R} = \{ h : h \text{ is analytic in } \mathbb{D}, h(0) = 0 = h'(0) - 1, \Re(h'(z)) > 0 \},$$

provides a univalent criterion. As a harmonic analog of it, Ponnusamy et al. [13], considered the class

$$K_1^H = \{ f = h + g \in H : \Re(h'(z)) > |g'(z)|, z \in \mathbb{D} \}.$$

We say that $f \in F S_H^*$ if $f \in S_H$ maps each subdisk $|z| < r$, $r \in (0, 1)$ onto a domain which is starlike with respect to the origin. Functions in $F S_H^*$ is then called a fully starlike in $\mathbb{D}$. We may set $F S_0^H := F S_H^* \cap H_0$ for obvious reason. Similarly, one can define the class of $F C_H^*$ of fully convex functions, and $F C_0^H := F C_H \cap H_0$. See [2] (also [8]) for a detailed discussion on fully starlike and fully convex functions.

Moreover, in [8], it was shown that $f = h + g \in F S_0^H \cap K_2^H$ whenever the coefficients of $h$ and $g$ given by (1.1) satisfy the condition

$$\sum_{n=2}^{\infty} n(|a_n| + |b_n|) \leq 1 - |b_1|,$$

where

$$K_2^H = \{ f = h + g \in H : |h'(z) - 1| < 1 - |g'(z)|, z \in \mathbb{D} \}.$$

Obviously, we may let $K_1^H = K_1^H \cap H_0$ and $K_2^H = K_2^H \cap H_0$.

Definition 2. Function $f \in \mathcal{H}$ is said to be fully convex of order $\alpha$ ($0 \leq \alpha < 1$) if it maps every circle $|z| = r < 1$ in a one-to-one manner onto a convex curve satisfying

$$\frac{\partial}{\partial \theta} \left( \arg \left( \frac{\partial}{\partial \theta} f(re^{i\theta}) \right) \right) > \alpha, \quad 0 \leq \theta < 2\pi, 0 < r < 1.$$

If $\alpha = 0$, then the harmonic mapping $f$ is said to be fully convex (univalent) in $\mathbb{D}$.

Definition 3. A function $f \in \mathcal{H}$ is said to be fully starlike of order $\alpha$ ($0 \leq \alpha < 1$) if it maps every circle $|z| = r < 1$ in a one-to-one manner onto a curve satisfying

$$\frac{\partial}{\partial \theta} \left( \arg \left( f(re^{i\theta}) \right) \right) > \alpha, \quad 0 \leq \theta < 2\pi, 0 < r < 1.$$

If $\alpha = 0$, then the harmonic mapping $f$ is said to be fully starlike (univalent) in $\mathbb{D}$.
Let $FS_h^\alpha(\alpha)$ and $FC_h(\alpha)$, respectively, denote the subclasses of $S_h$ consisting of fully harmonic starlike and fully harmonic convex functions of order $\alpha$. Also, set

$FS_h^0(\alpha) = FS_h^\alpha(\alpha) \cap H_0$ and $FC_h^0(\alpha) = FC_h(\alpha) \cap H_0$

so that $FS_h^0(0) = FS_h^\alpha(\alpha) \cap H_0$ and $FC_h^0(\alpha) = FC_h(\alpha) \cap H_0$. Jahangiri [6,7] gave a sufficient condition for functions $f \in H$ to be $FS_h^\alpha(\alpha)$ and $FC_h^\alpha(\alpha)$, respectively.

**Lemma 1.1.** Let $f = h + g \in H$, where $h$ and $g$ are given by (1.1). Furthermore, let

$$\sum_{n=2}^{\infty} \frac{n-\alpha}{1-\alpha} |a_n| + \sum_{n=1}^{\infty} \frac{n+\alpha}{1-\alpha} |b_n| \leq 1$$

and $0 \leq \alpha < 1$. Then $f \in FS_h^\alpha(\alpha)$.

**Lemma 1.2.** Let $f = h + g \in H$, where $h$ and $g$ are given by (1.1). Furthermore, let

$$\sum_{n=2}^{\infty} \frac{n(n-\alpha)}{1-\alpha} |a_n| + \sum_{n=1}^{\infty} \frac{n(n+\alpha)}{1-\alpha} |b_n| \leq 1$$

and $0 \leq \alpha < 1$. Then $f \in FC_h^\alpha(\alpha)$.

According to Rado-Kneser-Choquet theorem, a fully convex harmonic mapping is necessarily univalent in $D$. However, a fully starlike mapping need not be univalent (see [2]).

For $f = h + g \in S_h^0$ we let

$$D_f^\epsilon = zf_z - \epsilon f_z (|\epsilon| = 1)$$

and in the case of $\epsilon = 1$, we use the notation $D_f^{1} = Df$ for the sake of convenience. As with the analytic differential operator $zf'(z)$, the operators $Df$ and $\mathcal{G}f := D_f^{-1}$ play the important roles in harmonic mappings. In 1915, Alexander [1] proved that if $f \in S$, then $f(z) \in C$ if and only if $zf'(z) \in S^*$. In 1990, Shel-Small [14] gave one application of it to harmonic mappings as stated below.

**Theorem B.** If $f = h + g \in H$ is univalent, and has a starlike range and if $H$ and $G$ are the analytic functions on $D$ defined by

$$zH'(z) = h(z), \quad zG'(z) = -g(z), \quad H(0) = G(0) = 0,$$

then $F = H + G$ is univalent and has a convex range.

In general, the converse of Theorem B is not necessarily true. For example, if $F = L$, where $L = H_2 + G_2 \in C_H^0$ is the harmonic right half-plane mapping defined by (1.5), then it is easily seen that

$$DL(z) = zH'_2(z) - zG'_2(z)$$

is not starlike and moreover, it is not even univalent in $D$ (see [5, p. 110]). However, Ponnusamy and Sairam Kaliraj [10] proved the converse theorem with an additional condition as follows.
Theorem C. Suppose that \( F = H + \overline{G} \) is a sense-preserving normalized convex mapping, and \( DF = zF - \overline{z}F_\overline{z} \) is sense-preserving in \( \mathbb{D} \). Then \( DF \) is univalent and starlike in \( \mathbb{D} \).

The above discussions show that the question of univalency of the harmonic differential operator \( D_f \) is interesting. In this paper, we study mainly the radius of univalence, fully convexity and fully starlikeness of the harmonic differential operators \( D_f^\epsilon \) and \((1 - \lambda)f + \lambda D_f^\epsilon \) when the coefficients of \( h \) and \( g \) satisfy either (1.2) or (1.4). All these results are sharp.

2. Radius of starlikeness and convexity of \( D_f^\epsilon \)

In this section, we obtain the sharp radius of fully starlikeness and fully convexity of order \( \alpha \) for the harmonic differential operator \( D_f^\epsilon \). The following identities are useful in the proof of our results:

**Lemma 2.1.** We have

(a) \( \sum_{n=2}^{\infty} n r^{n-1} = \frac{r(2 - r)}{(1 - r)^2} \),

(b) \( \sum_{n=2}^{\infty} n^2 r^{n-1} = \frac{r(4 - 3r + r^2)}{(1 - r)^3} \),

(c) \( \sum_{n=2}^{\infty} n^3 r^{n-1} = \frac{r(8 - 5r + 4r^2 - r^3)}{(1 - r)^4} \),

(d) \( \sum_{n=2}^{\infty} n^4 r^{n-1} = \frac{r(16 + r + 11r^2 - 5r^3 + r^4)}{(1 - r)^5} \),

(e) \( \sum_{n=2}^{\infty} n^5 r^{n-1} = \frac{r(32 + 51r + 46r^2 - 14r^3 + 6r^4 - r^5)}{(1 - r)^6} \).

**Proof.** The proof of (a) follows from \( \sum_{n=1}^{\infty} n r^n = r(1 - r)^{-2} \) and the rest of them may be obtained by differentiating this and so on. \( \square \)

For \( 0 < r < 1 \) and \( f = h + \overline{g} \in \mathcal{H} \), let us define \( D_f^\epsilon \) by

\[
(2.1) \quad D_f^\epsilon(z) = \frac{D_f(rz)}{r} = z + \sum_{n=2}^{\infty} na_n r^{n-1} z^n - \epsilon \sum_{n=2}^{\infty} nb_n r^{n-1} z^n.
\]

**Theorem 2.2.** Let \( f = h + \overline{g} \), where \( h \) and \( g \) are given by (1.1), and the coefficients satisfy the conditions (1.2) for \( n \geq 2 \). Then for \( D_f^\epsilon = zf - \epsilon \overline{zf} \) \( (|\epsilon| = 1) \),

(1) the radius of fully starlikeness of order \( \alpha \) is \( r_\epsilon(\alpha) \), where \( r_\epsilon(\alpha) \) is the unique root of the equation \( p_\alpha(r) = 0 \) in the interval \( (0, 1) \), where

\[
(2.2) \quad p_\alpha(r) = 1 - \alpha - (17 - 9\alpha)r + (13 - 21\alpha)r^2 - 21(1 - \alpha)r^3 + 10(1 - \alpha)r^4 - 2(1 - \alpha)r^5,
\]
the radius of fully starlikeness is \( r_u \approx 0.0614313 \), where \( r_u \) is the unique root of the equation

\[
1 - 17r + 13r^2 - 21r^3 + 10r^4 - 2r^5 = 0
\]

in the interval \((0, 1)\).

All the results are sharp.

Proof. By the assumption \( h \) and \( g \) have the form (1.1) and the coefficients of the series satisfy the conditions (1.2). First, we observe that \( b_1 = g'(0) = 0 \). The conditions (1.2) imply that the series (1.1) are convergent in \( D \), and hence, \( h \) and \( g \) are analytic in \( D \). Thus, \( f = h + g \in H_0 \) for \( 0 < r < 1 \), it suffices to show that \( D_f^{\epsilon, r} \) defined by (2.1) with \( b_1 = 0 \) belongs to \( FS_H(\alpha) \).

Now, we consider

\[
S_1 = \sum_{n=2}^{\infty} \frac{n - \alpha}{1 - \alpha} |na_n|r^{n-1} + \sum_{n=2}^{\infty} \frac{n + \alpha}{1 - \alpha} |nb_n|r^{n-1}
\]

\[
\leq \sum_{n=2}^{\infty} \frac{n - \alpha}{1 - \alpha} \left( \frac{n(2n+1)(n+1)}{6} \right) r^{n-1}
+ \sum_{n=2}^{\infty} \frac{n + \alpha}{1 - \alpha} \left( \frac{n(2n-1)(n-1)}{6} \right) r^{n-1}
\]

\[
= \sum_{n=2}^{\infty} \frac{n^2 (1 - 3\alpha + 2n^2)}{3(1 - \alpha)} r^{n-1}
= \frac{1}{3(1 - \alpha)} \left[ \frac{(1 - 3\alpha) \left( 4 - 3r + r^2 \right)}{(1 - r)^3} + \frac{2r \left( 16 + r + 11r^2 - 5r^3 + r^4 \right)}{(1 - r)^5} \right]
= T_1
\]

where we have used Lemma 2.1(a) and (d) in the last equality. By Lemma 1.1, it suffices to show that \( T_1 \leq 1 \) which holds whenever \( p_{\alpha}(r) \geq 0 \), where \( p_{\alpha}(r) \) is defined by (2.2).

Now we shall show that the polynomial \( p_{\alpha}(r) \) defined by (2.2) has exactly one zero in the interval \((0, 1)\) for every \( \alpha \in [0, 1) \). Since \( p_{\alpha}(0) = 1 - \alpha > 0 \) and \( p_{\alpha}(1) = -16 < 0 \), so \( p_{\alpha}(r) \) has at least one zero in the interval \((0, 1)\). A straightforward calculation shows that

\[
p_{\alpha}'(r) = 9\alpha - 17 + 2(13 - 21\alpha)r - 63(1 - \alpha)r^2 + 48(1 - \alpha)r^3 - 10(1 - \alpha)r^4
= 9\alpha - 17 + 2(13 - 21\alpha)r - (1 - \alpha)r^2 \left[ 23 + 10(r - 2)^2 \right] \quad (\text{as } 0 < r < 1)
< 9\alpha - 17 + 2(13 - 21\alpha)r - 33(1 - \alpha)r^2 =: q_{\alpha}(r).
\]

It suffices to show that \( q_{\alpha}(r) \) is negative in the interval \((0, 1)\) for every \( \alpha \in [0, 1) \). Moreover,

\[
q_{\alpha}'(r) = 2 \left[ (13 - 21\alpha) - 33(1 - \alpha)r \right]
\]
which gives the critical point \( r_0 = \frac{13-21\alpha}{33(1-\alpha)} \) and \( q'_\alpha(r) > 0 \) for \( 0 \leq r < r_0 \) and \( q'_\alpha(r) < 0 \) for \( r_0 < r < 1 \). Clearly, we need to deal with the cases \( 0 \leq \alpha \leq 13/21 \) and \( 13/21 < \alpha < 1 \).

**Case 1.** Let \( 0 \leq \alpha \leq 13/21 \). We compute that
\[
q_\alpha(r_0) = \frac{8(20\alpha^2 - 39\alpha - 49)}{33(1-\alpha)} < 0 \quad \text{for} \quad 0 \leq \alpha \leq \frac{13}{21}.
\]
This implies that \( q_\alpha(r) < 0 \) in the interval \( r \in (0, 1) \) for all \( 0 \leq \alpha \leq 13/21 \).

**Case 2.** Let \( 13/21 < \alpha < 1 \). Then we have \( q'_\alpha(r) < 0 \) for \( r \in [0,1) \). Also, since \( q_\alpha(0) = 9\alpha - 17 < 0 \) and \( q_\alpha(1) = -24 < 0 \), we find that \( q_\alpha(r) < 0 \) in the interval \( r \in (0, 1) \) and for all \( 13/21 < \alpha < 1 \).

Combining the last two cases, we conclude that \( q_\alpha(r) < 0 \) in the interval \( (0, 1) \) and for all \( \alpha \in [0,1) \). This proves \( p'_\alpha(r) < q_\alpha(r) < 0 \) in the interval \( (0, 1) \) and for all \( \alpha \in [0,1) \). Thus, \( DF_r \in \mathcal{FS}_\alpha^{\ast}(\alpha) \) for \( r \leq r_\alpha(\alpha) \), where \( r_\alpha(\alpha) \) is the unique real root of Equation (2.2).

Note that the roots of Equation (2.2) in \( (0, 1) \) are decreasing as a function of \( \alpha \), \( 0 \leq \alpha < 1 \). Consequently, \( r_* \leq r_u \). Note that for \( \alpha = 0 \), Equation (2.2) reduces to (2.3). Then, by Lemma 1.1, we see that the harmonic function \( f \) is starlike and univalent in \( |z| \leq r_u \approx 0.0614313 \), where \( r_u \) is the unique root of the equation (2.3) in the interval \((0, 1)\).

Next, to prove the sharpness, we consider the function
\[
DF(z) = zH'(z) - zG'(z) = H_d(z) + \overline{G_d(z)},
\]
where
\[
H(z) = 2z - H_1(z) \quad \text{and} \quad G(z) = -G_1(z).
\]
Here, \( H_1(z) \) and \( G_1(z) \) are defined by (1.3). We note that
\[
DF(z) = z(2 - H_1'(z)) + zG_1'(z) = z \left( 2 - \frac{1 + z}{(1 - z)^2} \right) + \frac{z^2(1 + z)}{(1 - z)^3}.
\]
Direct computation leads to
\[
H_d'(r) = 2 - \frac{2r^2 + 5r + 1}{(1 - r)^4} \quad \text{and} \quad G_d'(r) = \frac{r (r^2 + 5r + 2)}{(1 - r)^5}.
\]
As \( DF(r) \) has real coefficients, we have
\[
J_{DF}(r) = (H_d'(r) + G_d'(r)) (H_d'(r) - G_d'(r))
\]
\[
= \left( 2 - \frac{2r^2 + 5r + 1}{(1 - r)^4} \right) \left( 2 - \frac{2r^2 + 5r + 2}{(1 - r)^5} \right)
\]
\[
= \frac{1 - 13r + 23r^2 - 19r^3 + 10r^4 - 2r^5}{(1 - r)^5}.
\]
Thus, \( J_{DF}(r) = 0 \) in \( (0, 1) \) if and only if \( r = r_u \approx 0.0614313 \) or \( r = r_u^* = 0.0903331 \), where \( r_u \) and \( r_u^* \) are the roots of
\[
1 - 13r + 23r^2 - 19r^3 + 10r^4 - 2r^5 = 0 \quad \text{and} \quad 1 - 17r + 13r^2 - 21r^3 + 10r^4 - 2r^5 = 0.
\]
in the interval \((0, 1)\), respectively. Moreover, for \(r_u < r < r_u^*\), we have \(J_{DF}(r) < 0\). The graph of the function \(J_{DF}(r)\) for \(r \in (0, 0.15)\) is shown in Figure 1. Therefore, in view of Lewy’s theorem, the function \(DF(z)\) is not univalent in \(|z| < 1\) if \(r > r_u\). This shows that \(r_u\) is sharp.

Furthermore,  
\[
\frac{\partial}{\partial \theta} \left( \arg \left( DF(re^{i\theta}) \right) \right) \bigg|_{\theta=0} = \frac{rH_d'(r) - rG_d'(r)}{H_d(r) + G_d(r)} = 1 - 17r + 13r^2 - 21r^3 + 10r^4 - 2r^5. 
\]
Thus, by (2.2) and \(p_\alpha(r_u(\alpha)) = 0\), we have  
\[
\frac{\partial}{\partial \theta} \left( \arg \left( DF(re^{i\theta}) \right) \right) \bigg|_{\theta=0, r=r_u(\alpha)} = \alpha. 
\]
This shows that \(r_u(\alpha)\) is the best possible.  

![Figure 1. The roots of the Jacobian \(J_{DF}(r)\) for \(r \in (0, 0.15)\).](image)

A slight change in the proof of Theorem 2.2 with the help of Lemma 1.2 yields the radius of fully convex for \(D^f\). So the proof is omitted here.

**Theorem 2.3.** Under the hypothesis of Theorem 2.2, for \(D^f = zf_z - \epsilon \bar{z}f_{z\bar{z}}\) \((|\epsilon| = 1)\) is fully convex of order \(\alpha\) in \(|z| < r_u(\alpha)\), where \(r_u(\alpha)\) is the unique root of the equation  
\[
1 - \alpha - 2(15 - 7\alpha)r - 12(1 + 3\alpha)r^2 - 2(29 - 21\alpha)r^3
\]
in the interval $(0,1)$. In particular, $D_f^r$ is fully convex in $|z| < r_c \approx 0.0328348$, where $r_c$ is the unique root of the equation
\[1 - 30r - 12r^2 - 58r^3 + 29r^4 - 12r^5 + 2r^6 = 0\]
in the interval $(0,1)$. All results are sharp.

**Theorem 2.4.** Let $f = h + \overline{g}$, where $h$ and $g$ are given by (1.1), and the coefficients satisfy the conditions (1.4) for $n \geq 2$. Then for $D_f^r = zf_z - \epsilon f_z f_z^*(|\epsilon| = 1)$,
1. the radius of full starlikeness of order $\alpha$ is $r_s(\alpha)$, where $r_s(\alpha)$ is the unique root of the equation $s(\alpha) = 0$ in the interval $(0,1)$, where
\[
s(\alpha) = 1 - \alpha - 6(2 - \alpha)r + 11(1 - \alpha)r^2 - 8(1 - \alpha)r^3 + 2(1 - \alpha)r^4,
\]
2. the (univalent) radius of fully starlikeness is $r_u \approx 0.0903331$, where $r_u$ is the unique root of the equation
\[1 - 12r + 11r^2 - 8r^3 + 2r^4 = 0\]
in the interval $(0,1)$.
All the results are sharp.

**Proof.** We follow the notation and the method of proof of Theorem 2.2. In order to prove (1) of Theorem 2.4, it suffices to show that $D_f^{r'} \in FS_H^{(2)}(\alpha)$, where $D_f^{r'}(z)$ is defined by (2.1). Accordingly, we consider
\[
S_2 = \sum_{n=2}^{\infty} \frac{n - \alpha}{1 - \alpha} |a_n| r^{n-1} + \sum_{n=2}^{\infty} \frac{n + \alpha}{1 - \alpha} |b_n| r^{n-1}
\leq \sum_{n=2}^{\infty} \frac{n - \alpha}{1 - \alpha} \left( \frac{n(n + 1)}{2} \right) r^{n-1} + \sum_{n=2}^{\infty} \frac{n + \alpha}{1 - \alpha} \left( \frac{n(n + 1)}{2} \right) r^{n-1}
= \sum_{n=2}^{\infty} \frac{n}{1 - \alpha} \left( \frac{n^2 - \alpha}{1 - \alpha} \right) r^{n-1}
= \frac{1}{1 - \alpha} \left[ \frac{r(8 - 5r + 4r^2 - r^3)}{(1 - r)^4} - \alpha r(2 - r) \right] =: T_2,
\]
where we have used Lemma 2.1(a) and (c) in the last equality. According to Lemma 1.1, it is sufficient to show that $T_2 \leq 1$, which is equivalent to $s(\alpha) \geq 0$, where $s(\alpha)$ is given by (2.4). Note that $s(0) = 1 - \alpha > 0$ and $s(1) = -6 < 0$ and so $s(\alpha)$ has at least one zero in the interval $(0,1)$. Since
\[
s'(\alpha) = -2 \left[ 3(2 - \alpha) + 11(1 - \alpha)r - 12(1 - \alpha)r^2 + 4(1 - \alpha)r^3 \right]
= -2 \left[ 3(2 - \alpha) + (1 - \alpha) \left( 4 \left( r - \frac{3}{2} \right)^2 + 2 \right) \right] < 0,
\]
\( s_\alpha(r) \) is strictly monotone decreasing in \((0, 1)\) and hence, \( s_\alpha(r) \) has exactly one root in \((0, 1)\) for all \( \alpha \in [0, 1) \). Thus, \( D_f^r \in \mathcal{FS}_H^0(\alpha) \) for \( r \leq r_\alpha(\alpha) \), where \( r_\alpha(\alpha) \) is the real root of \( s_\alpha(r) = 0 \) in the interval \((0, 1)\).

The second part (2) of Theorem 2.4 follows as before by setting \( \alpha = 0 \).

To prove the sharpness, we consider function \( DF(z) = H_d(z) + G_d(z) \) with
\[
H_d(z) = 2z - zH_d'(z) \quad \text{and} \quad G_d(z) = -zG_d'(z),
\]
where \( H_d(z) \) and \( G_d(z) \) are defined by (1.5). Direct computation yields
\[
H_d'(r) = 2 - \frac{1 + 2r}{(1 - r)^2} \quad \text{and} \quad G_d'(r) = \frac{r(2 + r)}{(1 - r)^4}.
\]
Again, since \( DF(r) \) has real coefficients, we obtain
\[
J_{DF}(r) = (H_d'(r) + G_d'(r)) (H_d'(r) - G_d'(r)) = \left( 2 - \frac{1 + 2r}{(1 - r)^2} + \frac{r(2 + r)}{(1 - r)^4} \right) \left( 2 - \frac{1 + 2r}{(1 - r)^2} - \frac{r(2 + r)}{(1 - r)^4} \right) = \frac{(1 - 8r + 13r^2 - 8r^3 + 2r^4)(1 - 12r + 11r^2 - 8r^3 + 2r^4)}{(1 - r)^4}.
\]
Thus, \( J_{DF}(r) = 0 \) in \((0, 1)\) if and only if \( r = r_u \approx 0.0903331 \) or \( r = r_v = 0.164878 \), where \( r_u \) and \( r_v \) are the roots of
\[
1 - 12r + 11r^2 - 8r^3 + 2r^4 = 0 \quad \text{and} \quad 1 - 8r + 13r^2 - 8r^3 + 2r^4 = 0
\]
in the interval \((0, 1)\), respectively. The graph of the function \( J_{DF}(r) \) for \( r \in (0, 0.25) \) is shown in Figure 2. Therefore, in view of Lewy’s theorem, the function \( DF(z) \) is not univalent in \( |z| < 1 \) if \( r > r_u \). This shows that \( r_u \) is the best possible.

Furthermore,
\[
\frac{\partial}{\partial \theta} \left( \arg(DF(re^{i\theta})) \right) \bigg|_{\theta = 0} = \frac{rH_d'(r) - rG_d'(r)}{H_d(r) + G_d(r)} = \frac{1 - 12r + 11r^2 - 8r^3 + 2r^4}{1 - 6r + 11r^2 - 8r^3 + 2r^4}.
\]
Thus, by (2.4) and \( s_\alpha(r_\alpha(\alpha)) = 0 \), we have
\[
\frac{\partial}{\partial \theta} \left( \arg(DF(re^{i\theta})) \right) \bigg|_{\theta = 0, r = r_\alpha(\alpha)} = \alpha.
\]
This shows that \( r_\alpha(\alpha) \) is the best possible.

The following result can be obtained by a similar argument as in the proof of Theorem 2.4, and so we omit the proof here.

**Theorem 2.5.** Let \( f = h + \overline{g} \), where \( h \) and \( g \) are given by (1.1), and the coefficients satisfy the conditions (1.4) for \( n \geq 2 \). Then \( D_f = zf_z - \epsilon \overline{zf_z} \ (|\epsilon| = 1) \) is fully convex of order \( \alpha \) in \( |z| < r_\alpha(\alpha) \), where \( r_\alpha(\alpha) \) is the unique root of the equation
\[
1 - \alpha - (23 - 10\alpha)r + (19 - 30\alpha)r^2 - (41 - 42\alpha)r^3 + (30 - 31\alpha)r^4
\]
Figure 2. The roots of the Jacobian $J_{DF}(r)$ for $r \in (0, 0.25)$.

$-12(1-\alpha)r^{5} + 2(1-\alpha)r^{6} = 0$

in the interval $(0, 1)$. In particular, $D_f$ is fully convex in $|z| < r_c \approx 0.0449935$, where $r_c$ is the unique root of the equation

$1 - 23r + 19r^2 - 41r^3 + 30r^4 - 12r^5 + 2r^6 = 0$

in the interval $(0, 1)$. All results are sharp.

3. Radius of the harmonic linear differential operator

$(1 - \lambda)f + \lambda D_f$

For $\lambda \geq 0$, let us introduce

$\mathcal{K}_H^{\lambda}(\lambda) = \{f = h + \overline{g} \in \mathcal{H} : \text{Re} (h'(z)) > |g'(z)|, \ z \in \mathbb{D}\},$

where $h_\lambda(z) = (h \ast \phi_\lambda)(z)$ and $g_\lambda(z) = (g \ast \phi_\lambda)(z)$, with

$\phi_\lambda(z) = (1-\lambda) \frac{z}{1-z} + \lambda \frac{z}{(1-z)^2} = \sum_{n=1}^{\infty} (1-\lambda + n\lambda) z^n.$

Similarly, we define

$\mathcal{K}_H^{2}(\lambda) = \{f = h + \overline{g} \in \mathcal{H} : |h'(z) - 1| < 1 - |g'(z)|, \ z \in \mathbb{D}\}.$

Also, we note that $\mathcal{K}_H^{1}(\lambda) := \mathcal{K}_H^{1}(0)$ and $\mathcal{K}_H^{2}(\lambda) := \mathcal{K}_H^{2}(0)$. Next, we observe that if $f \in \mathcal{K}_H^{1}(\lambda)$ and $F_\lambda(z) = h_\lambda(z) + \epsilon g_\lambda(z)$, then

$\text{Re} (F'_\lambda(z)) = \text{Re} (h'_\lambda(z) + \epsilon g'_\lambda(z)) \geq \text{Re} (h'_\lambda(z)) - |g'_\lambda(z)| > 0$
for each $|\epsilon| \leq 1$. Moreover, because $F_\lambda(z) = ((h + \epsilon g) \ast \phi_\lambda)(z)$, we see that

$$F'_\lambda(z) = (h'(z) + \epsilon g'(z)) \ast \left( \frac{\phi_\lambda(z)}{z} \right) = (h'(z) + \epsilon g'(z)) \ast \left( \sum_{n=1}^{\infty} (1 - \lambda + \lambda n) z^{n-1} \right)$$

so that

$$F'_\lambda(z) \ast \Psi_\lambda(z) = h'(z) + \epsilon g'(z), \quad \Psi_\lambda(z) = \sum_{n=1}^{\infty} \frac{z^n}{1 - \lambda + \lambda n}.$$ 

By the convolution result, since $\Psi_\lambda$ is convex in $\mathbb{D}$ and thus, $\text{Re} \left( \frac{\Psi_\lambda(z)}{z} \right) > 1/2$ in $\mathbb{D}$, it follows that $\text{Re} \left( h'(z) + \epsilon g'(z) \right) > 0$ in $\mathbb{D}$ and therefore, $h + \epsilon g$ is close-to-convex for each $|\epsilon| \leq 1$. Consequently, by Theorem A, the harmonic function $f = h + \bar{g}$ is close-to-convex in $\mathbb{D}$.

The following result follows immediately from [8], and we omit its proof.

**Theorem 3.1.** Let $f = h + \bar{g}$, where $h$ and $g$ have the form (1.1) with $J_f(0) = 1 - |b_1|^2 > 0$. If

$$\sum_{n=2}^{\infty} (1 - \lambda + \lambda n) n \left( |a_n| + |b_n| \right) \leq 1 - |b_1| \quad (\lambda \geq 0) \quad (3.1)$$

holds, then $f \in \mathcal{K}^2_H(\lambda)$.

**Theorem 3.2.** Let $h$ and $g$ have the form (1.1) and the coefficients of the series satisfy the conditions (1.2). Then, $f = h + \bar{g}$ satisfies the inequality

$$|h'_\lambda(z) - 1| < 1 - |g'_\lambda(z)| \quad (\lambda \geq 0) \quad (3.2)$$

in the disk $|z| < r_s$ and is fully starlike in $|z| < r_s$, where $r_s$ is the root of the equation

$$1 - (11 + 6\lambda)r + (21 - 8\lambda)r^2 - (19 + 2\lambda)r^3 + 10r^4 - 2r^5 = 0 \quad (3.3)$$

in the interval $(0, 1)$. The result is sharp.

**Proof.** By assumption (1.2), $f = h + \bar{g}$ is harmonic in $\mathbb{D}$. Let $0 < r < 1$. It suffices to show that the coefficients of $f_r(z) = r^{-1}f(rz)$ satisfy the inequality (3.1), where

$$f_r(z) = \frac{f(rz)}{r} = z + \sum_{n=2}^{\infty} a_n r^{n-1} z^n + \sum_{n=2}^{\infty} b_n r^{n-1} z^n. \quad (3.3)$$

By hypotheses

$$n (|a_n| + |b_n|) \leq \frac{n(2n^2 + 1)}{3}.$$
and thus, we compute
\[
S_3 = \sum_{n=2}^{\infty} (1 - \lambda + \lambda n)n(|a_n| + |b_n|)r^{n-1} \\
\leq \sum_{n=2}^{\infty} (1 - \lambda + \lambda n)^n \frac{n(2n^2 + 1)}{3} r^{n-1} \\
= \frac{1}{3} \sum_{n=2}^{\infty} \left[ 2\lambda n^4 + 2(1 - \lambda)n^3 + \lambda n^2 + (1 - \lambda)n \right] r^{n-1} =: T_3,
\]
which is less than or equal to 1 if \(T_3 \leq 1\), which is equivalent to
\[
1 - (11 + 6\lambda)r + (21 - 8\lambda)r^2 - (19 + 2\lambda)r^3 + 10r^4 - 2r^5 \geq 0.
\]
Thus, from Theorem 3.1, \(f_r(z) = r^{-1} f(rz)\) is close-to-convex (univalent) and fully starlike in \(D\) for all \(0 < r \leq r_s\), where \(r_s\) is the root of the equation (3.2) in the interval \((0,1)\). In particular, \(f\) is close-to-convex (univalent) and fully starlike in \(|z| < r_s\).

The proof of sharpness is similar to Theorem 2.2 and so we omit it here. \(\square\)

**Remark 1.** If \(\lambda = 0\) in Theorem 3.2, the equation (3.2) reduces to
\[
(1 - r) \left( 1 - 10r + 11r^2 - 8r^3 + 2r^4 \right) = 0.
\]
Thus, \(f_r(z) \in F \mathcal{S}_H^* \cap K_2 \mathcal{H}\) for \(r \leq r_s = 0.112903\), where \(r_s\) is the unique root of the equation
\[
1 - 10r + 11r^2 - 8r^3 + 2r^4 = 0.
\]
This gives the result obtained in [8, Lemma 1.2].

If \(\lambda = 1\) in Theorem 3.2, then the equation (3.2) reduces to the equation (2.3) in Theorem 2.2. Thus, the univalent radius is \(r_u \approx 0.0614313\), where \(r_u\) is the root of the equation (2.3).

**Corollary 3.3.** Let \(f = h + g\), where \(h\) and \(g\) are given by (1.1), and the coefficients satisfy the conditions (1.2) for \(n \geq 2\). Then the radius of fully starlikeness for \(F(z) = (1 - \lambda)f + \lambda D_f\) \((0 \leq \lambda \leq 1)\) is at least \(r_s\), where \(r_s\) is the root of the equation (3.2) in the interval \((0,1)\).

**Proof.** If we write
\[
F(z) = \frac{F(rz)}{r} = z + \sum_{n=2}^{\infty} A_n z^n + \sum_{n=2}^{\infty} B_n z^n,
\]
then
\[
A_n = [(1 - \lambda) + \lambda n] a_n r^{n-1} \quad \text{and} \quad B_n = [(1 - \lambda) + \tau \lambda n] b_n r^{n-1} \quad (\lambda > 0)
\]
so that
\[
n (|A_n| + |B_n|) \leq (1 - \lambda + \lambda n) (|a_n| + |b_n|) nr^{n-1} \leq (1 - \lambda + \lambda n) \frac{n(2n^2 + 1)}{3} r^{n-1}.
\]
Thus, we desired result follows from the proof of Theorem 3.2. \(\square\)
Theorem 3.4. Let $h$ and $g$ have the form (1.1) and the coefficients of the series satisfy the conditions (1.4). Then, $f = h + g \in K^2_\lambda(\lambda) \ (\lambda \geq 0)$ in the disk $|z| < r_c$ and is fully starlike in $|z| < r_c$, where $r_c$ is the root of the equation
\begin{equation}
1 - 4(2 + \lambda)r + (13 - 2\lambda)r^2 - 8r^3 + 2r^4 = 0
\end{equation}
in the interval $(0, 1)$. The result is sharp.

Proof. Clearly, it suffices to observe that
\begin{equation}
S_4 = \sum_{n=2}^{\infty} n(|a_n| + |b_n|) \leq n \left( \frac{n+1}{2} + \frac{n-1}{2} \right) = n^2
\end{equation}
and thus,
\begin{equation}
S_4 = \sum_{n=2}^{\infty} (1-\lambda+\lambda n)n(|a_n| + |b_n|)r^{n-1} \leq (1-\lambda) \sum_{n=2}^{\infty} n^2r^{n-1} + \lambda \sum_{n=2}^{\infty} n^3r^{n-1} =: T_4.
\end{equation}
It follows that $S_4 \leq 1$ if $T_4 \leq 1$ which is equivalent to
\begin{equation}
1 - 4(2 + \lambda)r + (13 - 2\lambda)r^2 - 8r^3 + 2r^4 \geq 0.
\end{equation}
The desired conclusion and the sharpness follow as before. \qed

If $\lambda = 0$ in Theorem 3.4, the equation (3.4) reduces to
\begin{equation}
(1-r)(1-7r+6r^2-2r^3) = 0
\end{equation}
and this gives the following result obtained in [8].

Theorem D. Let $h$ and $g$ have the form (1.1) and the coefficients of the series satisfy the conditions (1.4). Then, $f = h + g$ satisfies the inequality
\begin{equation}
|h'(z) - 1| < 1 - |g'(z)|
\end{equation}
in the disk $|z| < r_S \approx 0.164878$ and fully starlike in $|z| < r_S$, where $r_S$ is the root of the equation
\begin{equation}
1 - 7r + 6r^2 - 2r^3 = 0
\end{equation}
in the interval $(0, 1)$. The result is sharp.

If $\lambda = 1$ in Theorem 3.4, the equation (3.4) reduces to the equation (2.5) in Theorem 2.4(2). Moreover, by Lemma 1.1 and Theorem 3.4, we can easily obtain the following result.

Corollary 3.5. Let $f = h + g$, where $h$ and $g$ are given by (1.1), and the coefficients satisfy the conditions (1.4) for $n \geq 2$. Then the radius of fully starlikeness for $F(z) = (1-\lambda)f + \lambda D^\epsilon_f$ is at least $r_c$, where $r_c$ is the root of the equation (3.4) in the interval $(0, 1)$. The result is sharp.

Theorem 3.6. Let $h$ and $g$ have the form (1.1) with $|b_1| = |g'(0)| < 1$, and the coefficients satisfy the conditions
\begin{equation}
|a_n| + |b_n| \leq c
\end{equation}
for \( n \geq 2 \). Then, \( f = h + \overline{g} \in K_{2H}^2(\lambda) \) and is fully starlike in \( |z| < r_v \), where \( r_v \) is the root of the equation \( \Phi_{c,|b_1|,\lambda}(r) = 0 \) in the interval \((0,1)\), where

\[
\Phi_{c,|b_1|,\lambda}(r) = (1 + c - |b_1|)(1 - r)^3 - c[1 + (2\lambda - 1)r].
\]

The result is sharp.

**Proof.** We apply Theorem 3.1 and show that \( f_r \) defined by (3.3) belongs to \( K_{2H}^2(\lambda) \). As in the proofs of Theorems 3.2 and 3.4, it suffices to show that the corresponding coefficient inequality (3.1), namely,

\[
S_5 = \sum_{n=2}^{\infty} (1 - \lambda + \lambda n)(|a_n| + |b_n|)r^{n-1} + |b_1| r
\]

\[
\leq \sum_{n=2}^{\infty} (1 - \lambda + \lambda n)ncr^{n-1} + |b_1| \leq 1.
\]

By Lemma 2.1(a) and (b), the last inequality is easily seen to be equivalent to

\[
c \left[ (1 - \lambda) \frac{r(2 - r)}{(1 - r)^2} + \lambda \frac{r(4 - 3r + r^2)}{(1 - r)^3} \right] \leq 1 - |b_1|
\]

which upon simplification reduces to \( \Phi_{c,|b_1|,\lambda}(r) \geq 0 \). The result follows.

The function \( f_0 = h_0 + \overline{g_0} = (1 - \lambda)h_1 + \lambda h_1' + (1 - \lambda)g_1 + \lambda g_1' \), where

\[
h_1(z) = z - \frac{c}{2} \left( \frac{z^2}{1 - z} \right) \quad \text{and} \quad g_1(z) = -|b_1|z - \frac{c}{2} \left( \frac{z^2}{1 - z} \right),
\]

shows that the result is sharp. Note that

\[
J_{f_0}(r) = \frac{|h_0'(r)|^2 - |g_0'(r)|^2}{(1 - r)^3} \leq (1 + c - |b_1|)(1 - r)^3 - c[1 + (2\lambda - 1)r]
\]

which shows that \( J_{f_0}(r) > 0 \) for \( r < r_v \). The proof of the theorem is complete. \( \blacksquare \)

**Remark 2.** Take \( \lambda = 0 \) in Theorem 3.6, the equation (3.5) reduces to

\[
(1 - r) [(1 + c - |b_1|)(1 - r)^2 - c] = 0.
\]

Then \( f_r(z) \in FS_{2H}^* \) for \( r < r_S = 1 - \sqrt{\frac{c}{1 + c - |b_1|}} \). This result is due to Kalaj et al. \[8, Lemma 1.6\].
