# A Study on the Body Shape Analysis for an Avatar Generation of the Virtual Fitting System -Focusing on Korean Women in their 20's- 

Heekyung Jang • Jianhui Chen ${ }^{\dagger}$

Dept. of Fashion Design \& Engineering, Donghua University, China

#### Abstract

In the virtual fitting system, the use of a 3D avatar is not a simple garment model, but it should be able to reproduce the size and shape of the customer using a fitting system. Although various virtual fitting systems have their own 3D avatar sizing systems and provide 3D avatars that match the size of the customer, there are limitations in realizing the actual body shape in actual use by the consumer. The purpose of this study is to realize a 3D avatar with excellent size and conformity for customer use. Therefore, this study aims to provide basic data for the formation of a 3D standard avatar of Korean women aged in their 20's, by comparing and analyzing the degree of the consumer user friendly system change of a body type, and the consumer's ability in selecting a consumer representative body type. Based on the survey data of 'Size Korea' conducted from 2004 to 2015 at three times, we examined the change of body shape over 10 years. Then, based on the results of 6th and 7th data, 4 factors of the concurrent body shape change of women of the consumer demographic studied were selected through the use of a factor analysis. Following this analysis, the 4 extracted factors were clustered again and finally released 7 representative body types, which were obtained based on height and weight. The size of each representative figure is derived by the use of a regression analysis, and it is used as a basic data for 3D avatar formation of the virtual fitting system.

## I. Introduction

Presently, virtual fitting systems are being widely used as a method for evaluation of clothing fit. The simulation technology of the virtual fitting system has already reached a considerable level, and it is possible to express various forms of clothes and physical properties. However, it is difficult to represent the various body measurements by the 3D virtual body when it comes to a large number of consumers. In order to evaluate fit through the virtual fitting system, it is necessary to grasp the body shape and dimension of the consumer and implement the 3D virtual body based on the actual body shape and measurements.

The 3D virtual body is a tool for clothing design and try-on in the virtual fitting system. It can replace the different body characteristics as the standard of fitting. The 3D virtual body must be designed on the basis of statistical processing and body shape analysis of a certain sample of anthropometric data, and is highly representative of the specific human population characteristics. Therefore, the body shape is classified, and the coverage of the 3D virtual body is refined and expanded.

We would like to review some previous research for formation of 3D virtual body through human measurement information. Qi, Li, and Zhang, (2008) analyzed Chinese men's body based on 3D anthropometric data. Pan, Wang, Sha, \& Yu(2013) measured bodies of 18-25 years old women in northeastern provinces of China using both contact and non-contact measurement methods and analyzed the body shape based on statistical analysis and the Chinese clothing standard system. Na (2007) analyzed the shape of the trunk part based on the slope of the body shape and the vertical distance based on 3D human body scan images of American women. Shim (2002) conducted statistical analysis of anthropometric data to understand the body shape of middle-aged Korean women. Based on the difference of bust and hip circumference, she classified them into 3 body types and used them as basic data for a size system customized to middle-aged
women. Kim,S.R. and Jo,J.S.(2001) classified body type and standard of body type classification by statistical analysis of anthropometric data on 279 middle-aged women. Most of these studies form a 3D human body with data obtained through 3D human body scan, and conduct body shape analysis. 3D human body scan technology has been developed and used in the apparel industry since 2000. A 3D human body scanner can acquire the 3D shape of the human body in a short time and obtain body dimensions and information immediately. However, there are problems such as selection of the measurement site, high-cost facilities and technical problems, and limitations to the programs for forming an avatar. Therefore, in this study, body shape analysis is going to be conducted on the basis of traditional measurement data.
Age is an important factor in determining changes to the body shape; as age increases, the values related to size and weight increase. A study of body changes in adults aged 20-59 (Dong, 2008) showed that as age increased, height decreased and body weight increased. As age increases, the height measurements decrease, waist, abdomen, and hip increase, and the flexion of the waist becomes unclear. The neck and upper arms become thicker and the bust and hips droop. Thus there are many changes in body shape. The developmental process of adult women decreases the change of body weight at about 20 years of age. Therefore, in order to establish the standard for the size of the representative figure, this study intends to define the age range of the subject as a 20 -year-old adult woman.
The purpose of this study was to investigate the following:

1. Based on the data of the Korea Anthropometric Survey conducted three times from 2004 to 2015, it examined the change of body shape among 20 -year-old Korean women.
2. This study selected factors related to changes in body shape by factor analysis.
3. The study performed clustered analysis with selected factors. Classification was made by body type.
4. The study derived each representative body size by
regression equation.
5. The representative body size is provided as basic data of the follow-up avatar formation study.

## II. Methods and Procedures

## 1. Research Subjects and Materials

This study used data from the Korea Anthropometric Survey (Size Korea) conducted three times from 2004 to 2015. The subjects of the study were Korean women in their 20 's, viz. those in the 19-29 age group. The following Table 1 shows the number of measurement items, number of subjects, and the number of women in their 20 's.

## 2. Measurement Items

The measurement items of this study to analyze the body shape characteristics of women in their 20's are shown in Table 2 below. These items were selected by referring to 'Standard sizing system for clothe (1991)', 'Sizing systems for female adult's garments (2009)', and 'Location and method of anthropometric surveys for garments (2008)'. A total 81 items were selected and subdivided as 14 items of height, 22 items of circumference, 30 items of length, 6 items of breadth, 6 items of depth, 2 items of angle and 1 item of weight.

## 3. Research Method

The data of this study were statistically processed using SPSS program, and the research problems to be revealed in this study are as follows.
(1) Human body measurement data was analyzed as an essential element for forming a representative body type avatar. After eliminating the missing cases from the total measurements, the data are summarized and the statistical parts defined.
(2) F-test and T -test were conducted on the differences in measurements each year. The degree of body change over 10 years was compared and analyzed.
(3) Body type classification was performed based on the 6th and 7th data sets. The purpose of the body type classification was to form a 3D avatar that accurately reflects the characteristics of a specific body type and to obtain accurate parameters of human body parts required for forming a 3D avatar. The more the measurement items are, the more accurate the avatar expression will be. However, it is difficult to make an accurate conclusion because of many plural collinearities among various measurement items. In order to express the classification result more objectively and clearly, we combined many measurement items through factor analysis and extracted some factors independent of each other. These factors sufficiently reflect the characteristics of the human body and are free of the problem of

Table 1. Korea Anthropometric Survey (Size Korea)

| Times | Period | Number of <br> Measurement Items | Number of Subjects | Number of Women <br> (19~29 years old) |
| :---: | :---: | :---: | :---: | :---: |
| 5th | March 2003 ~ November 2004 | 359 items | $14200(0 \sim 9$ years old) | 942 |
| 6th | March 2010 ~ November 2010 | 139 items | $14016(7 \sim 69$ years old) | 1027 |
| 7th | May 2015 ~ December 2015 | 133 items | $6413(16 \sim 69$ years old) | 897 |

| Total | 81 |  |  |

collinearity between the measurement items. In order to better express human body characteristics, groups of similar body types were classified through cluster analysis. In this study, cluster analysis was performed on factors derived from factor analysis.
(4) The size of the representative body representing each cluster (each body type) was derived based on the above method. The stature, bust, and waist circumference were specified as the average size of each cluster, and the measures of the other items were derived through multiple regression equations based on the average size.
(5) Find out if the size of the representative body type obtained from the research is well expressed in the body of a women in their 20 's. It is provided as basic data of avatar formation research.

## III. Results and Discussion

## 1. Analysis of 5th, 6th, and 7th anthropometric measurements

The total descriptive statistics for 83 items related to Korean women in their 20's are shown in Table 3

Missing values were removed in a total of 2,814 cases.
The average size of 5 th, 6 th, and 7 th set is 160.25 cm in stature, 114.26 cm in bust height, 98.2 cm in waist height, and 79.14 cm in hip height. On the circumference side, the bust circumference is 83.53 cm , the waist circumference is 70.06 cm , and the hip circumference is 92 cm . The font waist length is 41.18 cm , and the back waist length is 42.14 cm , the back is a bit long. The bust breadth is 26.65 cm , waist breadth is 24.55 cm , and hip breadth is 32.38 cm . In the depth item, the chest is 20.81 cm , the waist is 17.35 cm , and the hip is 21.11 cm . The shoulder angle is about 1 degree difference between right and left, and the right side is more tilted. The Rohrer's Index was 1.32 and the BMI was 21.14, the obesity index shows normal.

## 2. Comparative analysis results of measurement data by year

The results of the F-test for measurement differences by year are shown in the following Table 4, Table 5, Table 6, Table 7, Table 8, and Table 9.

*p<.05, **p<.01, ***p<0.01

F-test results of the yearly measurements showed significant differences in 11 items among 14 items. There was no significant difference in stature, but the 7th data set showed the largest values for the hip, knee and crotch heights, and the 5th data set showed the largest value for the waist height. Coming to the 7th data set, it shows generally high values in the height items.

Looking at the proportion of vertical items to the stature, there was no significant difference in shoulder height; however, there were significant differences in axilla height, bust height and hip height. The proportions of the height difference in each part are as follows: the 5th data set has low hip position, the 6th data set has
an ideal ratio, and the 7th data set has high hip position.
The circumference items showed significant differences in all data sets. The 7th data had the largest values for almost all circumference items, and the 7th data had the smallest values for only the ankle and wrist circumferences. It was analyzed that major parts such as bust, waist, and hip circumference were larger than before. Looking at the drop dimensions to see the silhouette of the bust and hip based on the waist, the 5th data had the largest dimensions, followed by the 6th and 7th, respectively. Although the bust circumference became thicker in the order of 5th, 6th and 7th data
sets, the waist and hip circumference gradually become thicker compared to the bust circumference. Thus it is
understood that the curvature of the body became smaller with year.

*p<.05, **p<.01, ***p<0.01

The length items showed a dimensional difference over the years in all parts. The 7th data set showed the largest value in the waist front length and the waist back length. The shoulder length became shorter with the years in the order of 5th, 6th, and 7th data sets. The 7th data had the shortest value in the S.N.P to B.P length and, the B.P to B.P length. For the arm and related items, the upper arm to the lower arm length increased with year in all data sets, showing the largest value in the 7 th data set. The total crotch length became shorter with year in the order of 5th, 6th, and 7th data sets.This shows that the length between the waist and hip became shorter as seen from the height item.

The 5th data set was statistically recognized as the largest in terms of difference in the items related to waist front and waist back, and values in the 6th and 7th data sets were similar. In the difference between the length of interscye back and interscye front, the 6th data showed the largest value, and the 5th data showed the smallest value. In other words, length of the back center became gradually shorter than the front center, and length of the interscye front widened. Therefore, the body shape can be seen to be somewhat deteriorated.

All breadth items showed dimensional differences over the years. The 5th data set had the largest value in bust
breadth, and the 7th data set had the largest value in hip breadth. Looking at the ratio of body breadth to waist breadth, all items were the largest in the 5th data set, and the ratio became smaller in the order of 6th and 7th data sets. In other words, the bust breadth and hip breadth become relatively smaller as the waist breadth increases gradually. It is analyzed that the curvature of body decreases gradually as seen from the results of the circumference items.

All of the depth items showed dimensional differences over the years. The 7th data set showed the largest value in all items related to bust, waist, and hip. The body depth ratio based on waist depth showed the largest value in the 5th data set, followed by the 7th and the 6th in order. However, the difference between the actual measurements is insignificant and the visual difference is not significant.
In the flatness items, the 7 th data set shows the largest values of bust flatness. This is considered to show the largest value of bust protrusion compared to bust breadth. Waist flatness showed the largest value in the 5th data set, followed by the 6th and 7th in order. That is, it was analyzed that the waist area gradually changed into a flat body shape. In other words, it is analyzed that it takes a round shape from the upper body toward the lower body.

|  | BMI | 21.04 | 2.57 | 20.85 | 2.51 | 21.56 | 3.10 | 16.864*** | b b a |

Angle items were not measured for the 5th data set. Therefore, the 6th and 7th data were compared. The difference in angle is not large, but overall the right shoulder is judged to be dropped than the left shoulder. Obesity-related indexes such as Rohrer's Index and BMI showed the largest values in 7th data set. However, Rohrer's Index values were all in 1.30 range, and BMI values all in 21 range, showing that the degree of obesity is all normal.

## 3. Changes in Body Shape of Korean Women in Their 20's over the Past 10 Years

Based on the analysis, the body shape of Korean women in their 20's showed little change in stature over 10 years; however, body weight increased and major parts such as bust, waist, and hip circumference became larger than before. In terms of the height and length items, hip height increases gradually, vertical length of hip decreases
gradually, and the vertical length of thigh becomes longer. Among the circumference items, all the circumference values increased, but the differences in circumference between bust and waist and between waist and hip decreased. Thus the curvature of body decreased gradually. The same trend was also observed in the flatness items: bust flatness showed a gradually increasing trend, while flatness of the waist decreased gradually.

Length items became generally larger, but shoulder length became shorter. As the length difference between the back center and the front center became shorter and the length difference between the interscye of back and front became longer, the body shape can be seen to have become somewhat backward. On the shoulder angle part, the right shoulder drooped more than the left shoulder. Obesity indices, including Rohrer's Index and BMI

|  | BMI | 13.20 | 16.10 | 29.30 | 20.91 | 2.23 | 4.98 | 20.70 |

increased on account of the increase in body weight, but the degree of obesity is considered normal.

## 4. Extraction of Body Shape Change Factors by Factor Analysis

The analysis is based on the 6th and 7th data sets, which offer comparatively recent information among all the data without the missing measurement items. Based on Rohrer's Index, a total of 1,822 cases were analyzed after removing cases with index values less than 1.0 and more than 1.7. The results of statistical analysis are shown in the following Table 10.

Since it was not feasible to conduct factor analysis for all the measurement items, the analysis was performed on 50 major items indicating human body characteristics. 10 factors were extracted in the first factor analysis, but 4 factors were selected considering the screen-test result, and rotated orthogonally by Varimax method. The results of the factor analysis are shown in Table 11. 4 Factors constituting the body shape were extracted with a cumulative rate of $70.177 \%$.

The characteristics of the 4 extracted factors are as follows.

## Factor 1

It can be said to be a factor indicating 'the degree of obesity' by high load in all breadth, depth and circumference items. It has the greatest value among the 4 factors; the total value is 16.69 and the variance explanation power is 33.38 .

## Factor 2

It can be said to be a factor indicating 'the vertical length of the body' since it is highly loaded on all height items and vertical length items. If the value of this factor is high, it can be seen as a large body vertically. The total value is 11.640 and variance explanation power is 23.279.

## Factor 3

This factor represents the total crotch length,waist to hip length, and the body rise etc. It can be said that this factor represents the specifications from the waist to the hip. The total value is 3.798 and variance explanation power is 7.595 .

## Factor 4

The factor 4 includes items such as shoulder angle, shoulder breadth and length, interscye front and back length etc. This factor explains the degree of tilting of the shoulders, and size and shape of the shoulder and shoulder parts. The total value is 2.961 and variance explanation power is 5.923 .

## 5. Cluster Analysis

In order to better express body characteristics, we grouped them into similar body shapes by cluster analysis. There are various clustering methods, but the K-means Clustering Method was used in this study. This technique aims at partitioning the data into a specific number of clusters, defined a priori by the user, by minimizing the variations within-clusters.
In this study, the 4 factors extracted from the factor analysis were classified into 7 clusters by the K -means Clustering Method. The final modified cluster center table is presented in Table 12 below.
In the analysis of variance in Table 13, The cluster mean square caused by any of the 4 factor scores is much larger than the error mean square within the class. From the probability value, the probability that the 4 factor scores are less than $5 \%$. Regardless of which factor scores, the clustering results are clearer and the classification is clear.
The classified groups were named from tall to short in English alphabets Y, A, B based on height. Based on the degree of obesity, from thin to fat was named by the English alphabets S, M, F. Table 14 shows the number of cases and the share of each cluster.
For the total case (1822), 81 items were subjected to multivariate test and the test results are shown in Table 15 below. From the significance of the F test, it can be seen that no matter which test method, the significance probability is less than $5 \%$, that is, the original hypothesis is rejected (that is, there is no significant difference between the 7 body types), so it is concluded that: there are significant differences among the 7 body types. It proves reasonable to classify the entire case into 7 body types.

## 6. Representative Size of Each Body Type

The representative body size of each body type was calculated by referring to the Chinese standards for garments GB /T 1335. 2-2008. According to this standard, upper body items were calculated by applying multiple regression equation to the stature and bust circumference, and the lower body items were calculated by applying multiple regression equation to the stature and waist circumference. First, standard values of the stature, bust, and waist circumference of each body type are presented in Table 16 below. For ease of calculation, numbers after the decimal point were removed.
The multiple regression equation for stature and bust circumference (waist circumference) is as follows.

$$
\mathrm{y}=\beta(\mathrm{h}) \times \mathrm{m}+\beta(\mathrm{c}) \times \mathrm{n}+\varepsilon
$$

Here y is the specific part value, $\beta$ (h) is the regression coefficient of stature, $\beta$ (c) is the regression coefficient of the bust circumference (waist circumference), m is the stature value, n is the bust circumference (waist circumference) value, and $\varepsilon$ is a constant. Table 17 and Table 18 show the results of the variance analysis of the regression equation for the cervical height among the height items.
Since the correlation coefficient R is close to 1 , it can be seen that the linearity is close to the linear relationship between the independent variables (stature, bust circumference) and the dependent variable (cervical height).

Table 16. Reference Body Size by Cluster
(Unit:cm)

| Item | YM | BM | AM | AS | AF | BF | YS |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

Table 19. Representative Body Size by Body Type
(Unit:cm)

| Measurement Items |  | Body Type |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | YM | BM | AM | AS | AF | BF | YS |
| Height | Stature | 168.0 | 153.0 | 160.0 | 159.0 | 162.0 | 156.0 | 165.0 |
|  | Cervical Height(straight) | 143.2 | 128.8 | 135.4 | 134.6 | 137.4 | 131.8 | 140.2 |
|  | Acromion Height | 136.1 | 122.4 | 128.9 | 127.6 | 130.3 | 125.2 | 133.2 |
|  | Shoulder Height | 137.5 | 123.6 | 130.4 | 129.0 | 131.6 | 126.4 | 134.5 |
|  | Axilla Height | 125.1 | 112.6 | 118.6 | 117.6 | 119.4 | 114.9 | 122.9 |
|  | Elbow Height | 102.9 | 92.7 | 97.8 | 96.4 | 98.4 | 94.7 | 100.7 |
|  | Hip Height | 84.3 | 75.1 | 79.4 | 80.9 | 79.4 | 76.1 | 83.5 |
|  | Waist Height | 103.2 | 91.9 | 97.1 | 96.6 | 98.1 | 93.7 | 100.8 |
|  | Waist-Omphalion Height | 99.6 | 88.9 | 93.6 | 93.5 | 94.8 | 90.4 | 97.7 |
|  | Anterior-Superior Iliac Spine Ht. | 92.6 | 82.2 | 86.5 | 86.8 | 87.9 | 84.1 | 90.7 |
|  | Knee Height | 44.0 | 39.1 | 41.0 | 41.4 | 41.8 | 39.7 | 43.4 |
|  | Crotch Height | 77.4 | 69.1 | 72.1 | 73.6 | 73.4 | 70.3 | 76.7 |
|  | Lateral Malleolus Height | 6.6 | 6.1 | 6.3 | 6.2 | 6.4 | 6.2 | 6.5 |
|  | Bust Height | 120.5 | 108.3 | 114.0 | 113.5 | 114.9 | 110.0. | 118.6 |

Based on the AM type, the regression equation of the cervical height is as follows.
$0.784 \times 160+0.002 \times 82+9.845=135.449$
It is relatively close to the original size and displays up
to 1 decimal place for convenience of use. The value is 135.4. Regression equation for other items was performed through a similar process, and the sizes are given in Table 19 below.

Table 19. Continued

| Measurement Items |  | Body Type |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | YM | BM | AM | AS | AF | BF | YS |
| Bradth | Chest Breadth | 28.6 | 26.0 | 26.9 | 26.5 | 28.5 | 27.6 | 27.3 |
|  | Bust Breadth | 27.8 | 25.0 | 25.9 | 25.3 | 27.8 | 27.0 | 26.2 |
|  | Waist Breadth | 26.3 | 23.3 | 23.8 | 23.5 | 26.4 | 25.9 | 24.5 |
|  | Waist-Omphalion Breadth | 28.6 | 25.1 | 26.2 | 25.8 | 28.7 | 27.9 | 26.6 |
|  | Hip Breadth | 33.9 | 30.7 | 31.9 | 31.2 | 33.7 | 32.6 | 32.5 |
|  | Biacrominal Breadth | 36.6 | 34.1 | 34.5 | 34.9 | 36.3 | 35.2 | 35.8 |
| Depth | Armscye Depth | 10.3 | 9.1 | 9.1 | 8.9 | 10.4 | 10.3 | 9.2 |
|  | Chest Depth | 19.1 | 17.2 | 17.6 | 17.0 | 19.2 | 18.9 | 17.7 |
|  | Bust Depth | 22.3 | 19.5 | 20.3 | 19.1 | 22.4 | 21.8 | 20.2 |
|  | Waist Depth | 18.4 | 15.8 | 16.6 | 15.9 | 18.6 | 18.1 | 16.5 |
|  | Waist-Omphalion Depth | 19.0 | 16.6 | 17.2 | 16.5 | 19.3 | 18.9 | 17.1 |
|  | Hip Depth | 22.5 | 19.8 | 20.8 | 19.9 | 22.7 | 22.0 | 20.5 |

Through the above analysis, there are significant differences among the 7 body types. From the morphological point of view, the features of the 7 body types are as follows.
(1) In the Height items, the height ratio of each part to the stature is similar for all 7 body types. In the upper body length, BM is the shortest and YM is the longest. In the length from shoulder to bust, BM is the shortest and YM is the longest.
(2) In the circumference item, YM and AF are similar, YS and AM are similar, and AS and BM are similar. The circumference difference between the bust and waist and between the hip and waist become smaller in the order of M-F-S type. In other words, the M type is relatively curved, and the $S$ type is relatively less curved.
(3) Most vertical items in the length items are proportional to the stature. The hip vertical length becomes shorter in order of YM-AM-$\mathrm{AF}-\mathrm{YS}-\mathrm{AS}-\mathrm{BM}-\mathrm{BF}$, and the total crotch length become shorter in order of $\mathrm{YM}-\mathrm{AF}-\mathrm{AM}-\mathrm{YS}-\mathrm{BF}-\mathrm{AS}-\mathrm{BM}$. AM is relatively long in hip length, and AS is relatively short. The length difference between the front waist and the back waist becomes shorter in order of AS-YM-YS-BF-AM-BM-AF.
(4) In the breadth item, YM and AF are similar, YS and $A M$ are similar, and $A S$ and $B M$ are similar. The ratio of the bust to the waist breadth becomes smaller in order of $\mathrm{AM}-\mathrm{AS}-\mathrm{BM}-\mathrm{YS}-\mathrm{YM}-\mathrm{AF}-\mathrm{BF}$. The ratio of the
hip to the waist breadth becomes smaller in order of AM-AS-YS-BM-YM-AF-BF. The AM shows a relatively curved shape.
(5) In terms of depth, the ratio of the bust to the waist depth becomes smaller in order of BM-YS-AM-YM-AS-BF-AF. The ratio of the hip to the waist depth becomes smaller in order of $\mathrm{BM}-\mathrm{AM}-\mathrm{AS}-\mathrm{YM}-\mathrm{AF}-\mathrm{BF}$. The all flatness becomes smaller in order of $\mathrm{F}-\mathrm{M}-\mathrm{S}$ type. In other words, the S type shows relatively flat shape.

## IV. Conclusions

This study focuses on developing 3D avatars for fitting evaluation in the virtual fitting system. As a basic step, we analyzed the change of body shape in Korean women in their 20s and selected representative bodies for the 3D avatar.

1. Based on the survey data of Size Korean conducted three times between 2004 and 2015, we examined the change of body shape over 10 years. It was determined that there was little change of stature over 10 years, body weight increased gradually, and major parts such as bust circumference, waist circumference, and hip circumference became larger than before. Among the height and length items, hip height increases gradually, hip vertical length decreases gradually, and the vertical length of thigh becomes larger. Among the circumference
items, all the circumference parts increased, but the difference in circumference between bust and waist and between waist and hip decreased; thus the curvature of body decreased gradually. This trend was also observed in the flatness items; bust flatness showed a gradually increasing trend, and waist and hip flatness showed a gradually decreasing trend. Obesity index increased on account of the increase in body weight, but the degree of obesity is considered normal.
2. The Factor analysis was performed based on the 6th and the 7th anthropometric data sets, and 4 factors representing body characteristics of the target group were extracted. Factor 1 indicates the degree of obesity on account of high load in all breadth, depth, and circumference items. Factor 2 includes all height items and vertical length items, which indicate the vertical length of the body. Factor 3 indicates the characteristics from waist to hip. Factor 4 explains the degree of tilting of the shoulders, the size, and shape of the shoulder and shoulder parts.
3. The selected 4 factors were clustered and classified into 7 body types. The classified groups were named from tall to short in English alphabets Y, A, B based on height. Based on the degree of obesity, from thin to fat were named by English alphabets S, M, F. Accordingly, they were classified and named as YS, YM / AS, AM, $\mathrm{AF} / \mathrm{BM}, \mathrm{BF}$.
4. The body dimensions of each representative body type were derived by applying regression equations for each part of body, stature, bust circumference, and waist circumference.
5. As a result of the analysis, it is possible to represent the body characteristics of Korean women in their 20's with 7 body types. The 7 body shapes show a numerically morphologically valid difference, which is provided as data for the follow-up avatar formation study.
