Introduction

Severe dysmenorrhea in young women is usually primary dysmenorrhea, but cases with poor response to medical treatment may be due to endometriosis, adenomyosis, or Müllerian duct anomaly [1]. Juvenile cystic adenomyoma is a rare variant of adenomyosis characterized by the presence of a large hemorrhagic cyst resulting from extensive menstrual bleeding in ectopic endometrial glands [2]. Especially in young women, it can present as a focal cystic mass with severe dysmenorrhea, abdominal cramps, and pelvic pain resistant to medical treatment [3]. Currently, this unique entity has been renamed as accessory cavitated uterine mass (ACUM) [4]. ACUM is suggested to be a new variety of Müllerian anomaly that is usually located at the level of the insertion of the round ligament and is related to dysfunction of the female gubernaculum [4]. Therefore, ACUM closely mimics the unicorunate uterus with obstructed cavitated rudimentary horn, and differential diagnosis might not be easy even with the use of pelvic ultrasonography, hysterosalpingography, and magnetic resonance imaging (MRI) [5]. Confirmation of both ostia using hysteroscopy can be helpful in making an accurate diagnosis. Herein, we report two cases of successful laparoscopic mass excision in young women who complained of severe dysmenorrhea, diagnosed as ACUM, with a brief review of the literature.

Cases

1. Case 1
A 14-year-old girl complained of severe dysmenorrhea that had developed and progressively worsened since menarche at age 12 years. She experienced lower abdominal pain for more than 10 days around her menstrual period, along with nausea and vomiting. She had taken oral analgesics during these periods; however, they did not relieve the pain. She had to visit the emergency room and miss school several times. Her body weight was 47 kg, and her height was 157 cm. Physical examination revealed diffuse tender-
ness of the lower abdomen and bimanual pelvic examination was not performed because she was a virgin. Laboratory tests were all within normal limits.

Transrectal ultrasound revealed a 3-cm hyperechogenic mass on the right side of the uterus that was independent of the normal endometrium and ovaries. Pelvic MRI revealed a fluid collection in the right horn of the uterus. The preoperative MRI showed a bicornuate uterus with a noncommunicating horn (Fig. 1). After obtaining written consent, hysteroscopy was performed under general anesthesia, demonstrating a normal uterine cavity and bilateral ostia. Under general anesthesia with a muscle relaxant was used to avoid hymenal damage. Laparoscopy revealed a mass bulging out in the right anterior wall of the uterus. The myometrial wall over the cystic lesion was opened with monopolar scissors, and chocolate-like fluid was expelled from the cyst. The endometrial and myometrial tissue surrounding the cyst were completely resected using the monopolar hook. The myometrial defect was sutured by V-loc (Covidien, Mansfield, MA, USA) in two layers and reinforcedinterruptedly with 0-Polysorb Vicryl (Ethicon, Norderstedt, Germany) (Fig. 2). The abdominal cavity was thoroughly irrigated with saline, and the uterine wound was covered with Seperafilm (Genzyme Biosurgery, Framingham, MA, USA). The total operating time was 125 minutes, and the estimated blood loss was about 50 mL. Pathological examination showed a cyst wall lined with endometrial glandular epithelium and stromal cells surrounded by myometrium (Fig. 3). The postoperative period was uneventful. She was discharged 4 days after the operation. Her abdominal pain was completely resolved after surgery. She has had regular menstruation without complaints for 2 years after surgery.

2. Case 2
A 25-year-old nulligravida visited the emergency room with severe dysmenorrhea. Pelvic magnetic resonance imaging revealed a large cystic lesion (accessory cavitated uterine mass, asterisk) localized in the right side of the uterus, independent of the normal endometrium and ovaries. EM, endometrial cavity.
abdominal pain in the left lower quadrant. The urologist examined her first and ruled out the possibility of renal stones or other urological disorders. She had a history of erratic severe lower abdominal pain refractory to medical treatment. She showed a tender abdomen without rebound tenderness or costovertebral tenderness. Pelvic ultrasound revealed a 3-cm hypoechogenic mass on the left side of the uterus, which did not communicate with the endometrial cavity. The presumptive diagnosis of pelvic MRI was a unicor- nuate uterus with a rudimentary horn containing hemorrhage (Fig. 4). However, in the operative field, a smooth protruding mass was found on the left anterior wall of the uterus, with both ovaries and tubes grossly intact. We also ruled out unicornuate uterus by confirming that the uterine cavity and ostia were normal, using hysteroscopy. Laparoscopic mass excision was performed. On pathological examination, the cyst wall was lined with endometrial glandular epithelium and stromal cells, surrounded by myometrium. Adenomyotic lesions were not revealed in the surrounding myometrium (hematoxylin and eosin stain, ×100).

**Discussion**

The typical feature of juvenile cystic adenomyoma or ACUM is early-onset severe dysmenorrhea, which usually starts soon after

---

**Fig. 3.** Histological section showing cyst wall lined with endometrial stromal cells, surrounded by myometrium (hematoxylin and eosin stain, ×200).

**Fig. 4.** Pelvic magnetic resonance imaging revealing a large cystic lesion (accessory cavitated uterine mass, asterisk) localized in the left side of the uterus, apart from the normal endometrium. Polycystic ovaries were also found. EM, endometrial cavity.

**Fig. 5.** (A) The excised specimens are irregularly shaped cystic structure with focal hemorrhage. (B) Histologic section showing the cyst wall lined with endometrial glandular epithelium and stromal cells, surrounded by myometrium. Adenomyotic lesions were not revealed in the surrounding myometrium (hematoxylin and eosin stain, ×100).
ACUM in young women with severe dysmenorrhea

Cystic adenomyomas or ACUMs are mostly located in the lateral wall near the uterine round ligament attachment site. They mimic uterine anomalies such as a unicornuate uterus with a rudimentary horn, bicornuate uterus with a noncommunicating horn, and hematometra in uterine didelphys with a transvaginal septum. Additionally, the degenerated myoma and vesicouterine endometrioma are also considered as differential diagnoses [12]. ACUM is a cystic lesion that is independent of the normal endometrium, whereas hematomata and hematocolpos are present in the obstructing Müllerian anomaly [10]. Even with MRI, it can sometimes be difficult to differentiate it from a cavitated noncommunicating rudimentary uterine horn. In this situation, hysterosalpingography and hysteroscopy can be useful in distinguishing it from a uterine anomaly [5]. In our case, the patients were young and complained of unbearable severe dysmenorrhea that developed and progressively worsened from menarche. Therefore, obstructive Müllerian anomaly was first considered, and the interpretation of preoperative MRI was also a uterine anomaly with a noncommunicating horn. However, hysteroscopy showing a normal uterine cavity and ostia were helpful in making the differential diagnosis.

On pathological examination, ACUM is characterized by ectopic endometrial epithelium, glands, and/or stroma within the myometrium. A well-demarcated region of myometrial hyperplasia borders the endometrial tissue and appears as a thick-walled, well-circumscribed lesion within the uterine muscle [14,15].

Initial empirical treatment, including oral contraceptives and analgesia, can be attempted. However, ACUM is usually resistant to medical treatment, and surgical removal might be unavoidable. Laparoscopic excision has been attempted and has shown good postoperative results, comparable to those of exploratory laparotomy [10]. Other surgical approaches have been proposed, such as radiofrequency ablation under ultrasonography guidance [16], single incision with monopolar cauterity [17], or the use of robotic surgery [18].

In the cases presented, ACUM was diagnosed in two young women, one a 14-year-old adolescent girl and a 25-year-old young woman, both presenting with complaints of unbearable severe dysmenorrhea. Laparoscopic mass excision successfully resolved the dysmenorrhea. Early investigation of severe dysmenorrhea in young women can help with appropriate management and reduce the duration of symptoms.
